

# TRAINING DEEP NEURAL NETWORKS II

**EE 541 – UNIT 7**

## TOPIC OUTLINE

- Universal Approximation Theorem
  - Why Deep?
- A Gentle Introduction to PyTorch
- Vanishing gradient and activations
- Weight initialization
- Cost functions, regularization, dropout
- Optimizers
- Batch Normalization
- Hyperparameter optimization

# COST (LOSS) FUNCTIONS

## COST (LOSS) FUNCTIONS

some already covered, but let's review and see how they translate to PyTorch

simplified notation:

$\mathbf{s}$  last layer pre-activation (linear activation)

$\mathbf{a} = \mathbf{h}(\mathbf{s})$  last layer activation

$\mathbf{y}$  labels

Assume  $M$  output nodes, so these are  
 $M \times 1$  vectors

## LOSS FUNCTIONS – L2 FOR REGRESSION

$$C = \|\mathbf{y} - \mathbf{a}\|_2^2 = \sum_{i=1}^M (y_i - a_i)^2$$

(squared) L2 norm of error  
or sum of squared error

$$C = \frac{1}{M} \|\mathbf{y} - \mathbf{a}\|_2^2 = \frac{1}{M} \sum_{i=1}^M (y_i - a_i)^2$$

average squared error

*these are equivalent*

PyTorch implements the mean by default, see options  
*(good since it is normalized for number of classes)*

for BP Initialization

$$\frac{d}{da} (y - a)^2 = 2(y - a)$$

```
1 ms = nn.MSELoss()
2 output = ms(
3     torch.FloatTensor([[1, 1, 1], [2, 2, 2]]),
4     torch.FloatTensor([[0, 0, 0], [3, 3, 3]]))
5
6 tensor(1.)
```

## LOSS FUNCTIONS – L1 FOR REGRESSION

$$C = \|\mathbf{y} - \mathbf{a}\|_1 = \sum_{i=1}^M |y_i - a_i|$$

L1 norm of error  
or sum of absolute error

$$C = \frac{1}{M} \|\mathbf{y} - \mathbf{a}\|_1 = \frac{1}{M} \sum_{i=1}^M |y_i - a_i|$$

average absolute error

*these are equivalent*

PyTorch implements the mean by default, see options  
(good since it is normalized for number of classes)

for BP Initialization

```

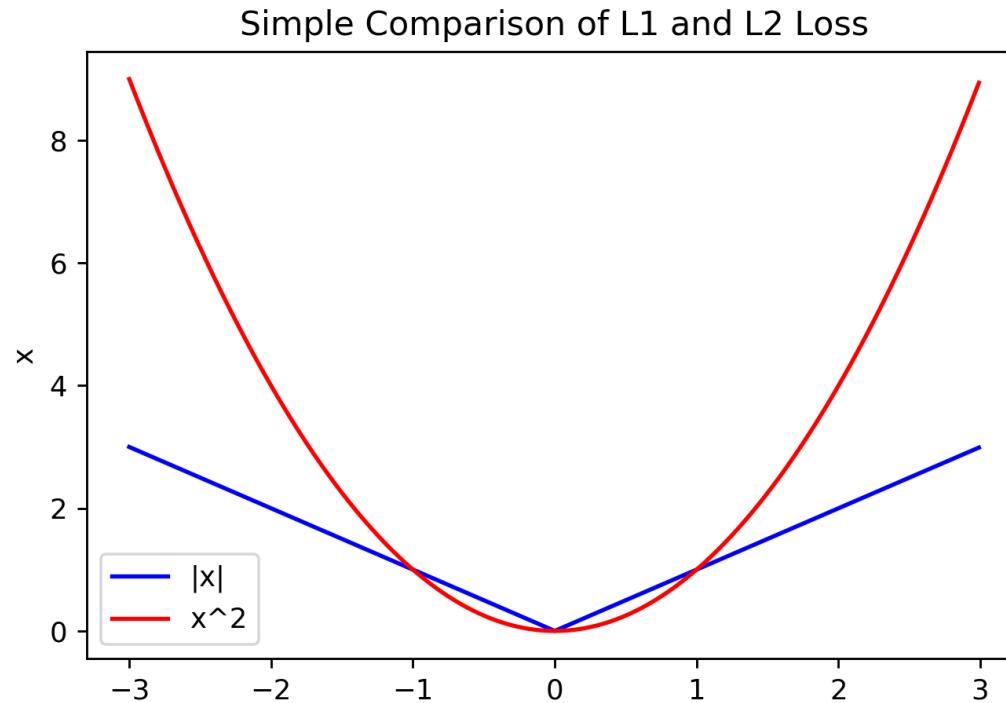

1 ms = nn.L1Loss()
2 output = ms(
3     torch.tensor([[1., 1., 1.], [1., 1., 1.]]),
4     torch.tensor([[0., 0., 0.], [3., 3., 3.]]))
5
6 tensor(1.5000)

```

$$\frac{d}{da} |y - a| = \text{sgn}(y - a) \\ = \begin{cases} +1 & a > y \\ -1 & a < y \end{cases}$$

## LOSS FUNCTIONS – L1 VS L2

L2 penalizes large error more than L1

L2 corresponds to power/energy for ECE

L1 will typically induce sparsity in your weights - allows a few large weights and many other weights are near 0

## LOSS FUNCTIONS – MULTICATEGORY CROSS ENTROPY

$$C = - \sum_{i=1}^M y_i \ln a_i = \sum_{i=1}^M y_i \ln \left( \frac{1}{a_i} \right)$$

BP gradient initialization:  $\delta^{(L)} = a^{(L)} - y$

If activations are outputs of a softmax then interpret  
as probability of class  $i$

# LOSS FUNCTIONS – MULTICATEGORY CROSS ENTROPY

Recall with one-hot (hard labels)

$$C = - \sum_{i=1}^M y_i \ln a_i$$

$$C = - \ln a_m$$

Class  $m$  is true

```
5 loss_func = nn.CrossEntropyLoss()
6 loss_func(
7     torch.tensor([
8         [np.log(0.9), np.log(0.05), np.log(0.05)],
9         [np.log(0.05), np.log(0.89), np.log(0.06)],
10        [np.log(0.05), np.log(0.01), np.log(0.94)]]
11    ),
12    torch.tensor([0,1,2])
13 ).numpy()
```

array(0.09458991)

$$(np.log(0.9) + np.log(0.89) + np.log(0.94)) / 3 \\ = -0.094590$$

(averaged over batch size)

recall: MCE is the negative log-likelihood  
(NLL) with regression error model:

$$P(class = i) = a_i$$

## LOSS FUNCTIONS – MULTICATEGORY CROSS ENTROPY

Recall that with soft labels we use the general form

$$C = - \sum_{i=1}^M y_i \ln a_i$$

```
1 def categorical_cross_entropy(y_pred, y_true):
2     return -(y_true * torch.log(y_pred)).sum(dim=1).mean()
3
4
5 categorical_cross_entropy(
6     torch.tensor([
7         [0.9, 0.05, 0.05],
8         [0.05, 0.89, 0.06],
9         [0.05, 0.01, 0.94]]),
10    ),
11    torch.tensor([
12        [0.7, 0.2, 0.1],
13        [0.05, 0.9, 0.05],
14        [0.3, 0.3, 0.4]]))
15 )
16 )
tensor(1.2243)
```

PyTorch does not include soft-label loss function

Define your own (left)  
or use nn.KLDivLoss

recall: KL-divergence is a constant offset from MCE  
between the  $y$  and  $a$  probability mass functions

## COST (LOSS) FUNCTIONS – BINARY CROSS ENTROPY

for  $M = 2$  outputs – binary classification

$$C = -y \ln(a) - (1 - y) \ln(1 - a) = y \ln\left(\frac{1}{a}\right) + (1 - y) \ln\left(\frac{1}{1 - a}\right)$$

Same as MCE with  $a_0 = a, a_1 = 1 - a$

PyTorch uses this

```
1 nn.BCELoss()(  
2     torch.tensor([[.6, .8, .1]]),  
3     torch.tensor([[0., 1., 0.]]))  
4 )  
  
tensor(0.4149)  
  
def bce(y,a):  
    return -1*y*np.log(a+1e-10) -(1-y)*np.log(1-a+1e-10)  
  
np.mean(bce(np.array([0,1,0]), np.array([0.6, 0.8, 0.1])))  
0.414932
```

Compare with `nn.BCEWithLogitsLoss()`

## CROSS ENTROPY LOSS – “FROM LOGITS”

numerically simpler (and more stable) to compute  
Loss(activation(s)) in one step

*example: binary cross entropy*

$$C = -y \ln(a) - (1 - y) \ln(1 - a)$$

$$a = \sigma(s)$$

$$= [1 + e^{-s}]^{-1}$$

$$C = y \ln(1 + e^{-s}) + (1 - y) \ln(1 + e^{+s})$$

$$= \ln(1 + e^{-\bar{y}s})$$

$$\bar{y} = (-1)^y$$

$$C = \ln(1 + e^{-\bar{y}s})$$

loss directly from linear activation

Use this if you do not need a pmf out of your trained model

– *i.e.*, if you will threshold the outputs of the trained model

Compare with `nn.NLLLoss()`

## CROSS ENTROPY LOSS – “FROM LOGITS”

numerically simpler (and more stable) to compute  
Loss(activation( $s$ )) in one step

*example: multiclass cross entropy*

$$C = - \sum_{i=1}^M y_i \ln \left[ \frac{e^{s_i}}{\sum_j e^{s_j}} \right]$$

$$= - \sum_{i=1}^M y_i [s_i - K(\mathbf{s})]$$

$$= - \sum_{i=1}^M y_i s_i + K(\mathbf{s})$$

$$K(\mathbf{s}) = \ln \left( \sum_j e^{s_j} \right)$$

$$C = K(\mathbf{s}) - \sum_{i=1}^M y_i s_i$$

loss directly from linear activation

$$C = K(\mathbf{s}) - s_m$$

Class  $m$  is true, hard labels

## CROSS ENTROPY LOSS – “FROM LOGITS”

$$K(\mathbf{s}) = \ln \left( \sum_j e^{s_j} \right)$$
$$= \max_j^* s_j$$

$$\begin{aligned}\max^*(x, y) &= \ln(e^x + e^y) \\ &= \max(x, y) + \ln(1 + e^{-|x-y|}) \\ \max^*(x, y, z) &= \ln(e^x + e^y + e^z) \\ &= \max^*(\max^*(x, y), z)\end{aligned}$$

numerically stable approach

loss directly from linear activation:

$$C = \max_j^* s_j - \sum_{i=1}^M y_i s_i$$

$$C = \max_j^* s_j - s_m$$

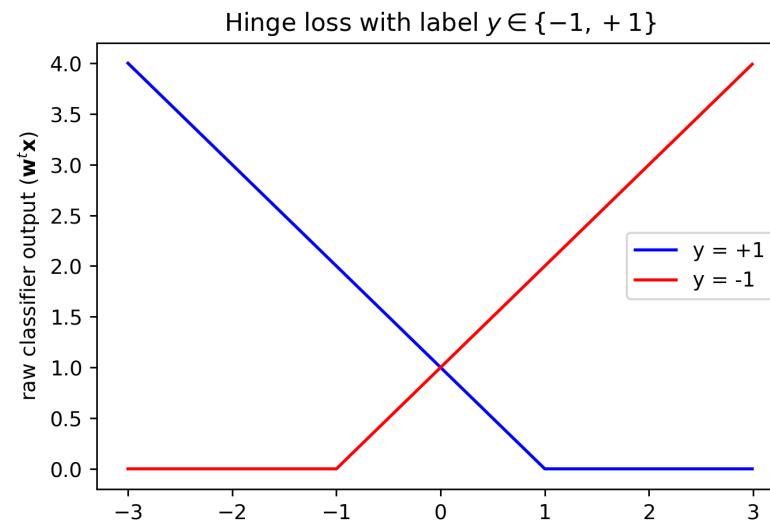

Class  $m$  is true, hard labels

# HINGE LOSS

for binary classifier with target/labels in  $\{-1, +1\}$

penalize misclassification (threshold)

$$C = \max(1 - ya, 0) \quad a = s, y \in \{-1, +1\}$$

typically use linear output activation

`torch.nn.MarginRankingLoss, margin=1`

# PYTORCH LOSS FUNCTIONS

`nn.L1Loss`

Creates a criterion that measures the mean absolute error (MAE) between each element in the input  $\mathbf{x}$  and target  $\mathbf{y}$ .

`nn.MSELoss`

Creates a criterion that measures the mean squared error (squared L2 norm) between each element in the input  $\mathbf{x}$  and target  $\mathbf{y}$ .

`nn.CrossEntropyLoss`

This criterion combines `nn.LogSoftmax()` and `nn.NLLLoss()` in one single class.

`nn.CTCLoss`

The Connectionist Temporal Classification loss.

`nn.NLLLoss`

The negative log likelihood loss.

`nn.PoissonNLLLoss`

Negative log likelihood loss with Poisson distribution of target.

`nn.KLDivLoss`

The Kullback-Leibler divergence loss measure

`nn.BCELoss`

Creates a criterion that measures the Binary Cross Entropy between the target and the output:

`nn.BCEWithLogitsLoss`

This loss combines a *Sigmoid* layer and the *BCELoss* in one single class.

`nn.MarginRankingLoss`

Creates a criterion that measures the loss given inputs  $\mathbf{x1}$ ,  $\mathbf{x2}$ , two 1D mini-batch *Tensors*, and a label 1D mini-batch tensor  $\mathbf{y}$  (containing 1 or -1).

# CUSTOM LOSS FUNCTIONS

PyTorch = simple custom loss functions

```
def my_loss(output, target):
    loss = torch.mean((output - target)**2)
    return loss

model = nn.Linear(2, 2)
x = torch.randn(1, 2)
target = torch.randn(1, 2)
output = model(x)
loss = my_loss(output, target)
loss.backward()
print(model.weight.grad)
```

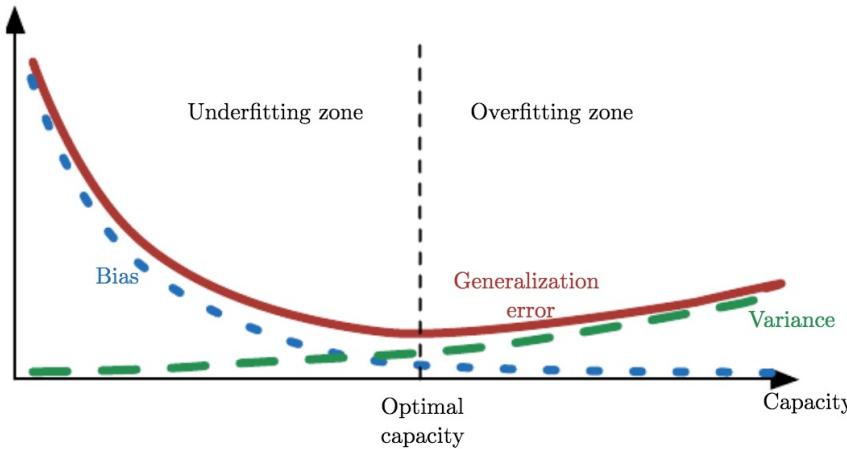

reimplementation of `nn.MSELoss`

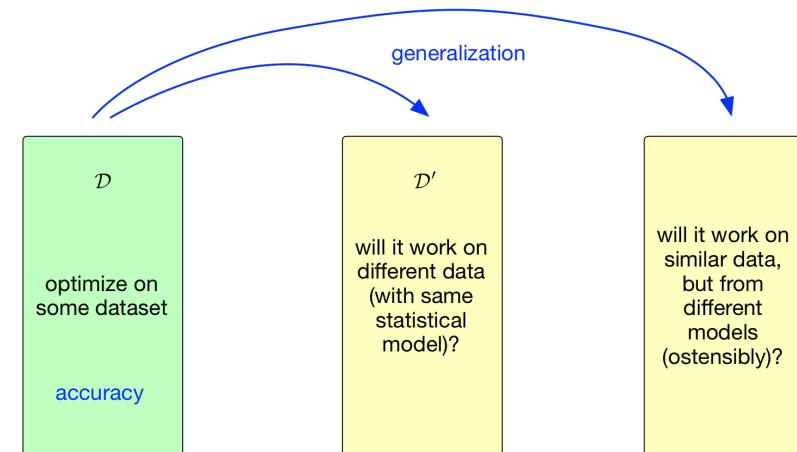

# WEIGHT REGULARIZATION

# WHY REGULARIZE

trade-off between over and under fitting  
is the Bias-Variance trade-off

Main goal of  
Machine Learning  
is to GENERALIZE

# REGULARIZERS

Main goal of Machine Learning is to  
**GENERALIZE**

regularization is anything you do in training that is aimed at  
improving generalization over accuracy –  
i.e., anything that does not optimize the cost on the training data

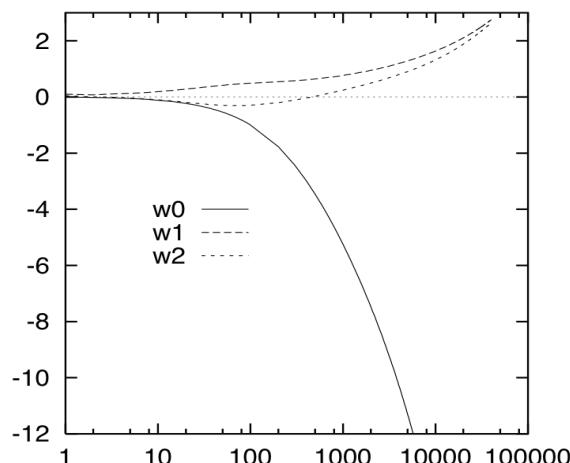

When people say “regularizer” they usually mean a narrower definition:

an additive term to the loss function that prevents  
weights from getting too large

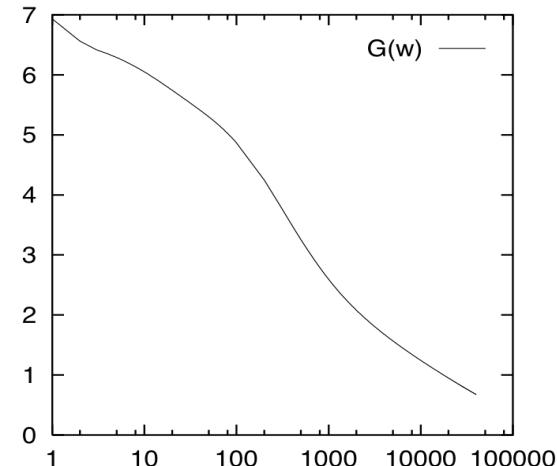

# HOW TO REGULARIZE

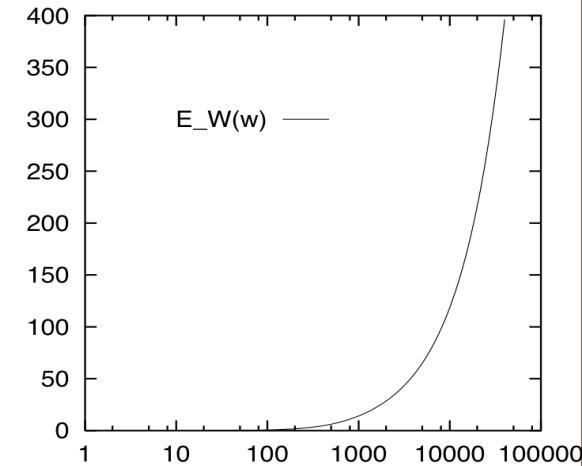

Why do large weights correspond to over-fitting???

weight evolution

learning curve (loss)

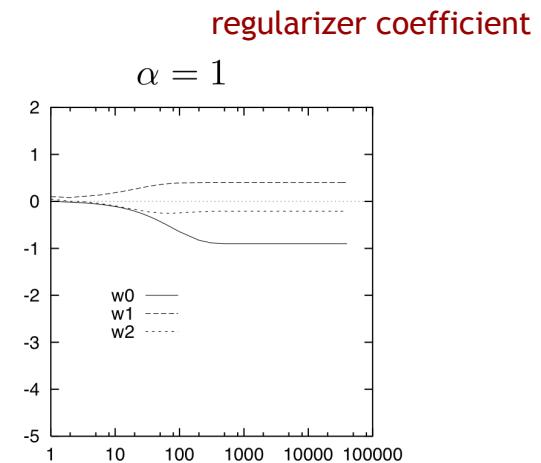

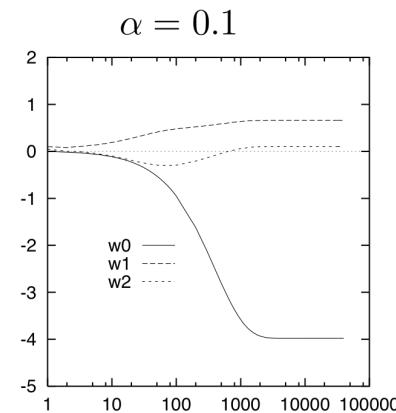

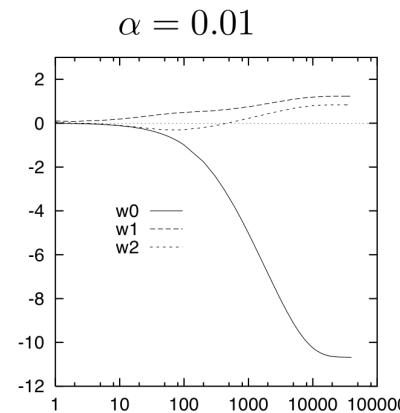

L2 norm of weights

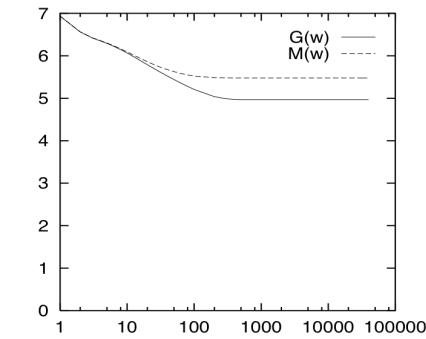

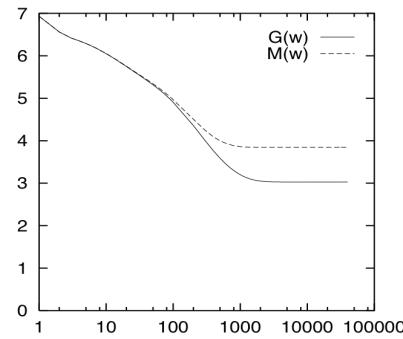

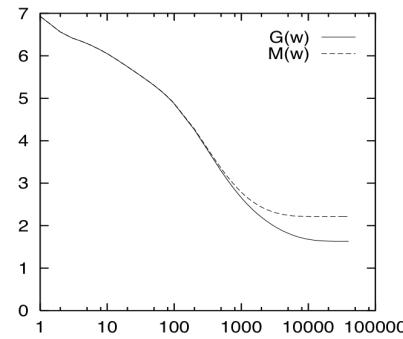

# HOW TO REGULARIZE

This is an experimental observation

weight evolution  
(L2 regularization)

learning curve (loss)

## REGULARIZERS – L1, L2

L2 regularization  
*(weight decay)*

$$C = C_{\text{no-reg}} + \lambda \|\mathbf{w}\|_2^2$$

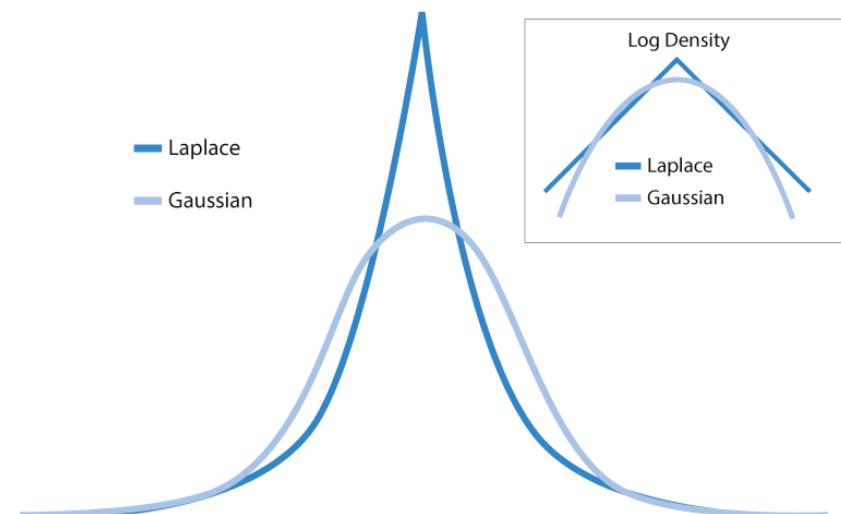

$$\longrightarrow w \leftarrow w - \eta \left( \frac{\partial C}{\partial w} + 2\lambda w \right)$$

L1 regularization  
*(LASSO)*

$$C = C_{\text{no-reg}} + \lambda \|\mathbf{w}\|_1$$

$$\longrightarrow w \leftarrow w - \eta \left( \frac{\partial C}{\partial w} + \lambda \text{sgn}(w) \right)$$

As we saw earlier: these can be viewed as being induced by an *a priori* distribution on the weights with MAP weight estimation

L2: Gaussian prior

L1: Laplace prior

# REGULARIZERS

$$\lambda \approx \frac{\text{Importance of small weights}}{\text{Importance of minimizing training loss}}$$

$$\lambda = 0 \quad \longrightarrow \quad w^* \sim \arg \min C_{\text{no-reg}}(\mathbf{w})$$

could be over-fitting, depends on capacity of model, dataset properties, and inference problem

$$\lambda = \infty \quad \longrightarrow \quad w^* \sim 0$$

under-fitting

Typically:  $10^{-5} \lesssim \lambda \lesssim 10^{-3}$

# REGULARIZERS IN PYTORCH

<https://pytorch.org/docs/stable/optim.html>

CLASS `torch.optim.SGD(params, lr=<required parameter>, momentum=0, dampening=0, weight_decay=0, nesterov=False)`

[SOURCE]

Implements stochastic gradient descent (optionally with momentum).

Nesterov momentum is based on the formula from [On the importance of initialization and momentum in deep learning](#).

## Parameters

- **params** (*iterable*) – iterable of parameters to optimize or dicts defining parameter groups
- **lr** (*float*) – learning rate
- **momentum** (*float, optional*) – momentum factor (default: 0)
- **weight\_decay** (*float, optional*) – weight decay (L2 penalty) (default: 0)
- **dampening** (*float, optional*) – dampening for momentum (default: 0)
- **nesterov** (*bool, optional*) – enables Nesterov momentum (default: False)

```
1 optim.SGD([
2     {'params': model.base.parameters(), 'weight_decay': 0.},
3     {'params': model.classifier.parameters(), 'weight_decay': 0.01}
4 ], lr=1e-2)
```

Use per-parameter options for more control

Most optimizers include a **weight\_decay** parameter  
 $L^2$  penalty, default = 0

works with autograd package

# REGULARIZERS IN PYTORCH

But how to back-propagate with regularized loss???

```
1 l1_regularization, l2_regularization = torch.tensor(0), torch.tensor(0)
2
3 optimizer.zero_grad()
4 outputs = model(inputs)
5 cross_entropy_loss = F.cross_entropy(outputs, targets)
6
7 for param in model.parameters():
8     l1_regularization += torch.norm(param, 1)
9     l2_regularization += torch.norm(param, 2)**2
10
11 loss = cross_entropy_loss + l1_regularization + l2_regularization
12 loss.backward()
13 optimizer.step()
```

autograd keeps track!

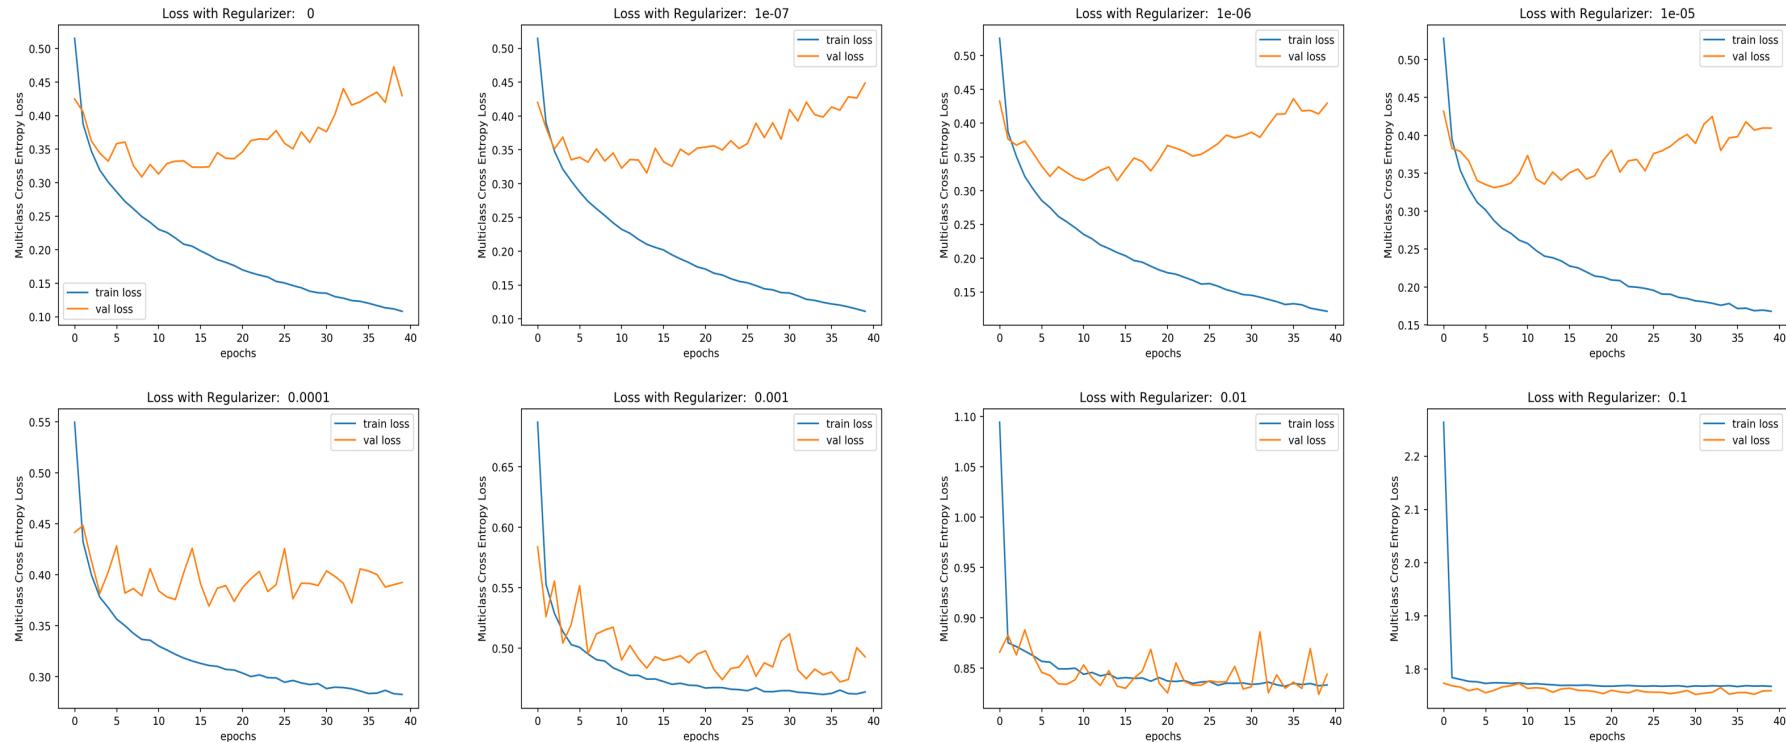

```
1 ## x in range [0, 1]
2 x = torch.rand(3,2,requires_grad=True)
3 loss = torch.sum(torch.abs(x))
4 loss.backward()
5 ## gradient should be all one
6 x.grad
```

```
tensor([[1., 1.],
        [1., 1.],
        [1., 1.]])
```

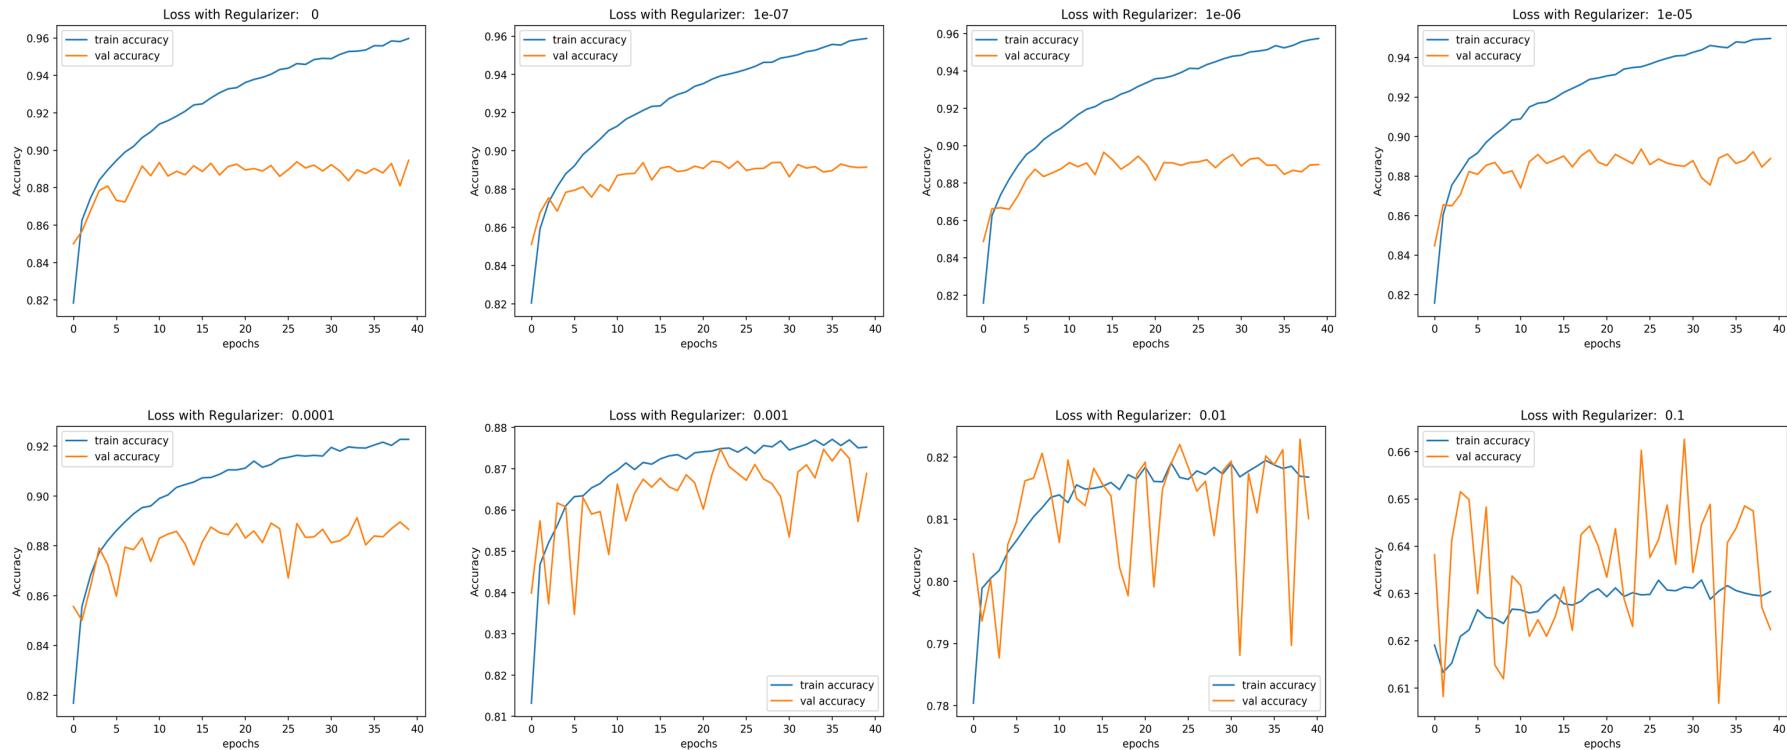

# LET'S TRY L2 REGULARIZATION...

just using regularization, we need  $\lambda \sim 1e-3$  to prevent overfitting, but the loss is much higher (~0.45 vs 0.1)

# LET'S TRY L2 REGULARIZATION...

same trend as the loss...  
(note: this is with 80/20 train/loss split)

*not totally satisfying!*

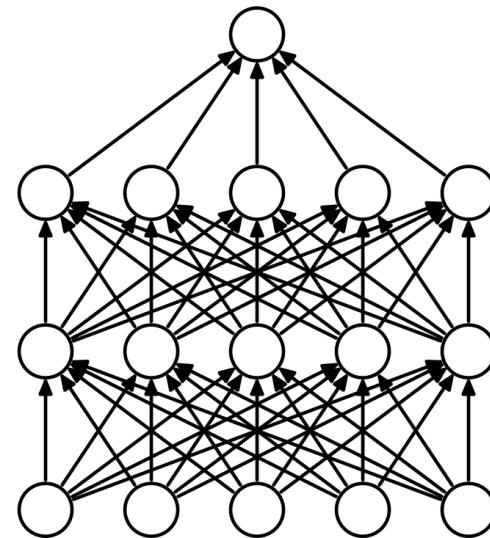

# DROPOUT REGULARIZATION

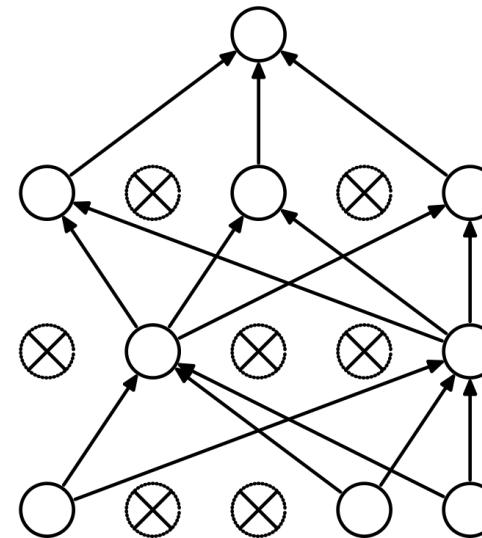

## DROPOUT – A DIFFERENT TYPE OF REGULARIZATION

remove nodes in a layer with some dropout probability/rate

the random pattern is generated at the start of each mini-batch  
and held fixed during that mini-batch

(a) Standard Neural Net

(b) After applying dropout.

# DROPOUT

very effective at reducing over fitting and improving generalization

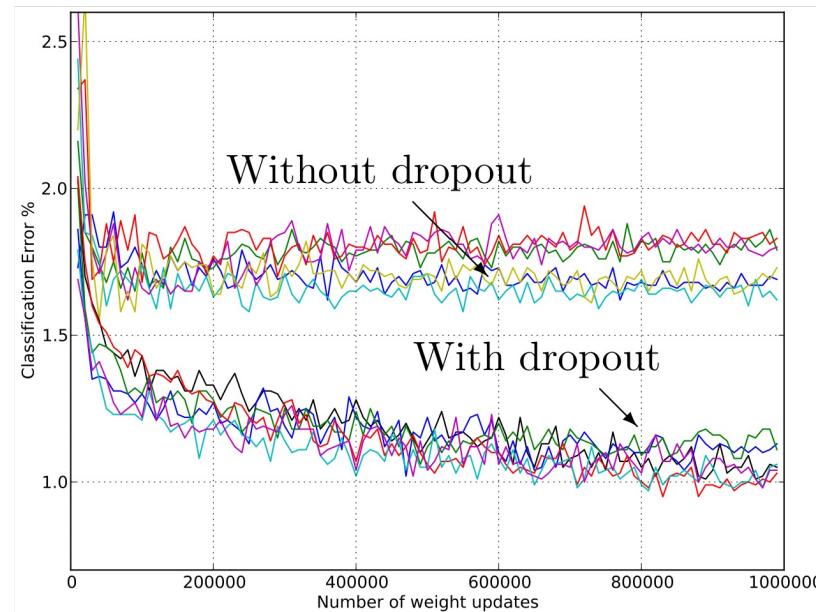

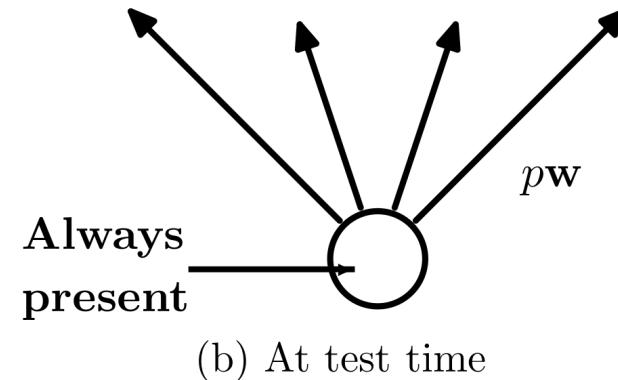

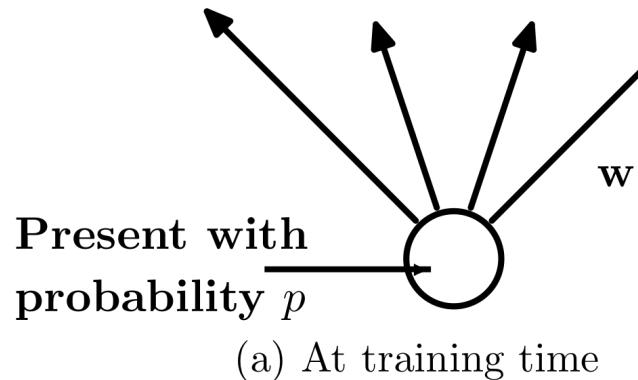

Figure 4: Test error for different architectures with and without dropout. The networks have 2 to 4 hidden layers each with 1024 to 2048 units.

## DROPOUT – ONLY DURING TRAINING!

Dropout is used during training, but in inference mode, all nodes are present

for inference, replace the trained weights with  $p \cdot w$ ,  
where  $(1 - p)$  is the dropout rate

*(ad hoc due to nonlinearities, but it works well enough)*

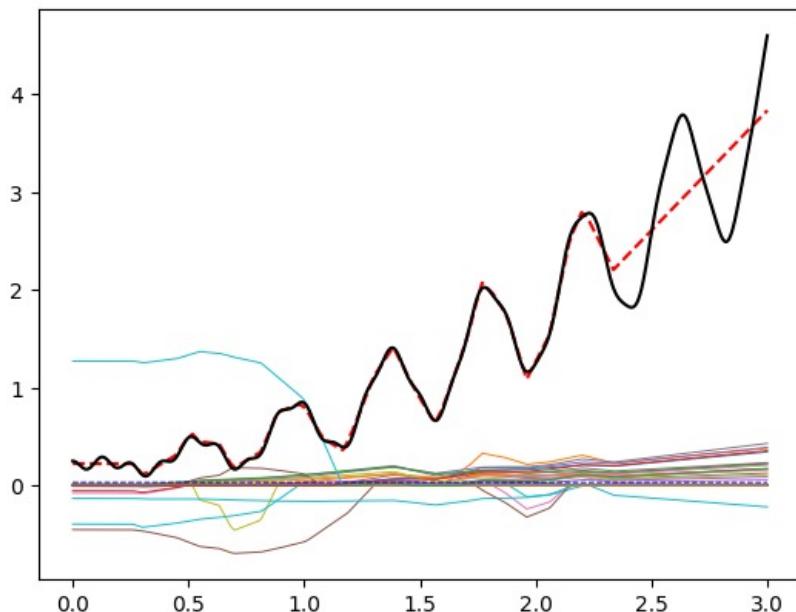

# DROPOUT EXAMPLE

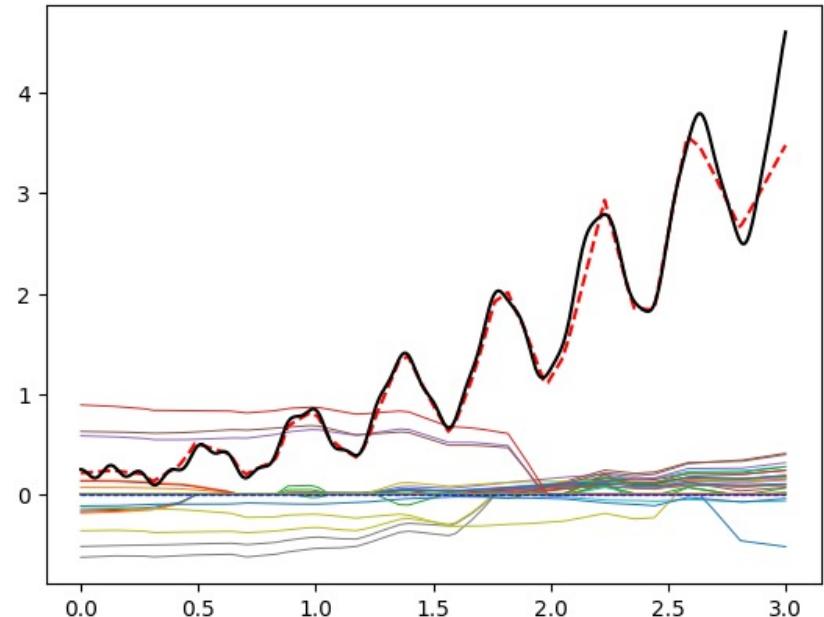

What happens when we train a neural net on Neilson's nonlinear function?

```
def neilson_example(x):
    | return 0.2 + 0.4 * x**2 + 0.3 * x * np.sin(15 * x) + 0.05 * np.cos(50 * x)
```

3 hidden layers, 64 nodes each, ReLU activations

no dropout

20% Dropout

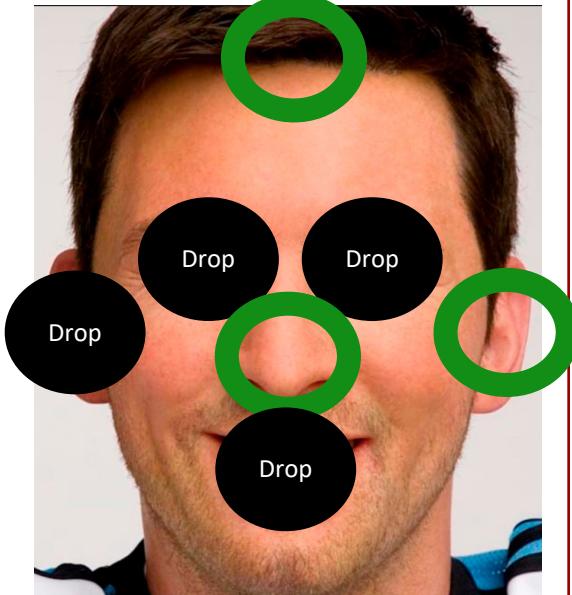

## DROPOUT INTUITION

Ensemble methods: train multiple networks for same task and average

Dropout can be viewed as an efficient way to do this in a single network

individual (or small groups of) nodes must do a reasonable job on the task w/o  
the deleted nodes lead to Robustness/Generalization

# DROPOUT IN PYTORCH – JUST ANOTHER LAYER

```

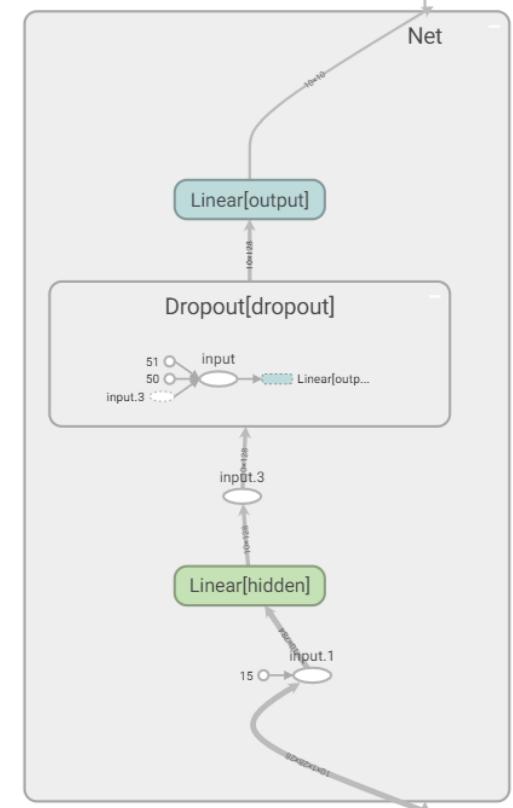

1 import torch
2 import torch.nn as nn
3 import numpy as np
4 import torch.nn.functional as F
5
6 class Net(nn.Module):
7     def __init__(self):
8         super(Net, self).__init__()
9         self.hidden = nn.Linear(28*28, 128)
10        self.dropout = nn.Dropout(p=0.3)
11        self.output = nn.Linear(128, 10)
12
13    def forward(self, x):
14        x = F.relu(self.hidden(x))
15        x = self.dropout(x)
16        x = self.output(x)
17        return x
18
19 model = Net()
20
21 from torchsummary import summary
22 summary(model, input_size=(1, 1, 28*28))

```

Layer (type)	Output Shape	Param #
Linear-1	[ -1, 1, 1, 128]	100,480
Dropout-2	[ -1, 1, 1, 128]	0
Linear-3	[ -1, 1, 1, 10]	1,290

Total params: 101,770  
Trainable params: 101,770  
Non-trainable params: 0

Input size (MB): 0.00  
Forward/backward pass size (MB): 0.00  
Params size (MB): 0.39  
Estimated Total Size (MB): 0.39

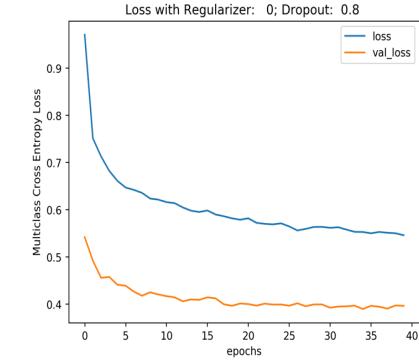

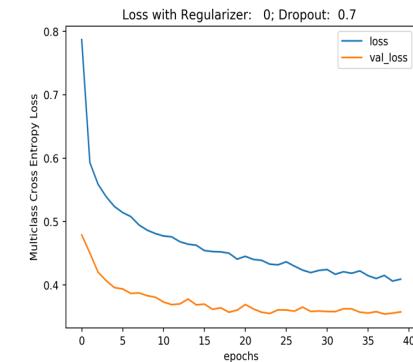

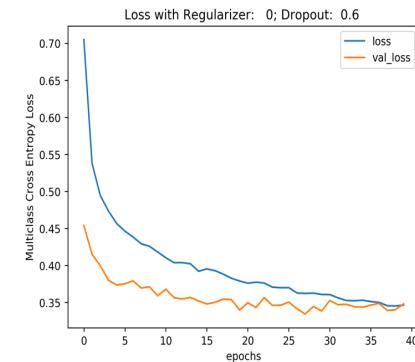

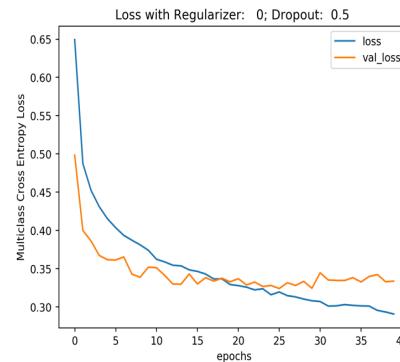

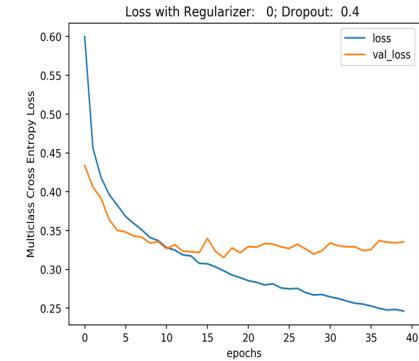

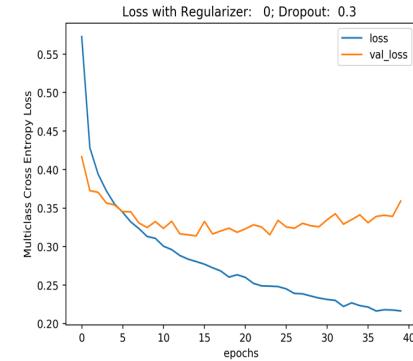

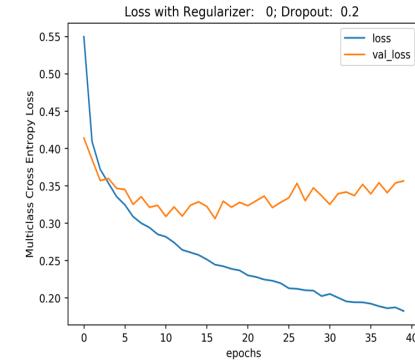

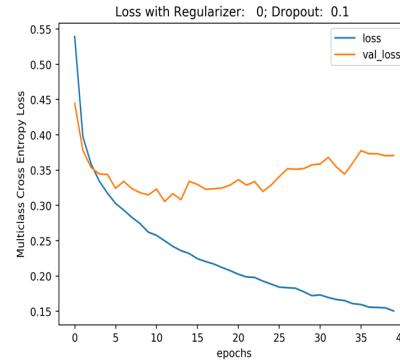

Dropout layer has no trainable parameters –it is an on/off *mask* that follows each node in the Dense layer

some layers have dropout built-in (e.g., RNNs)

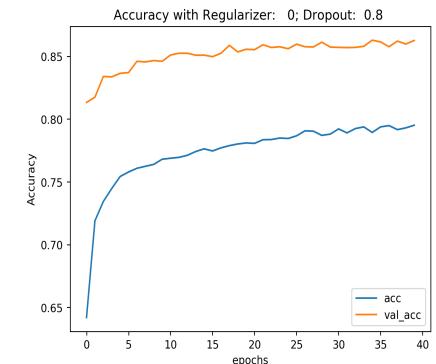

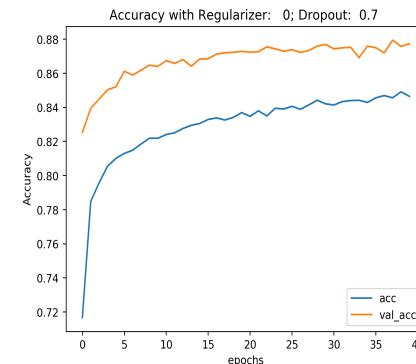

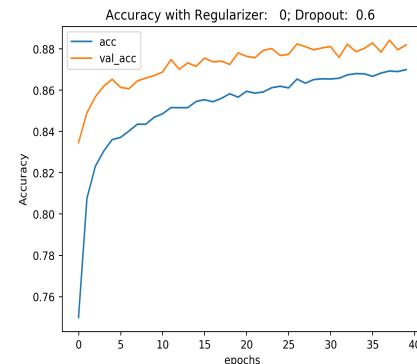

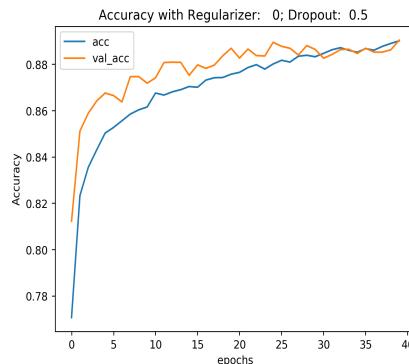

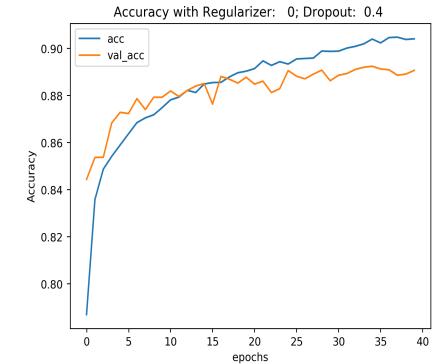

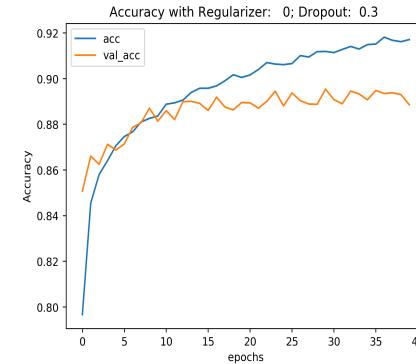

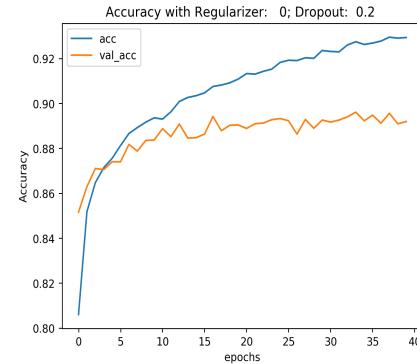

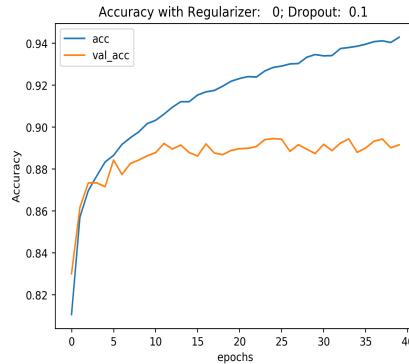

# DROPOUT WITH NO L2 REGULARIZATION

with dropout of ~ 60%, we are not over-fitting and we have a loss of ~ 0.35  
(better than L2 regularization in this case)

# DROPOUT WITH NO L2 REGULARIZATION

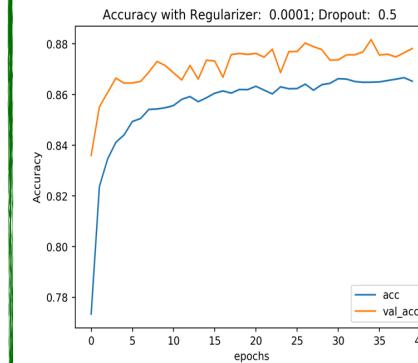

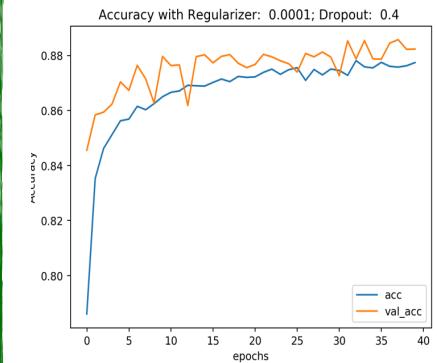

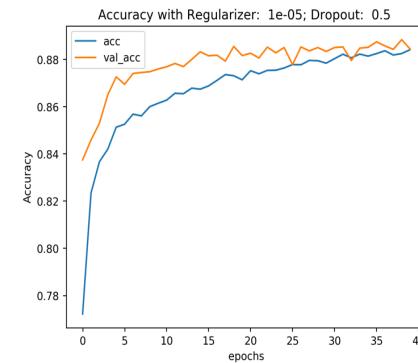

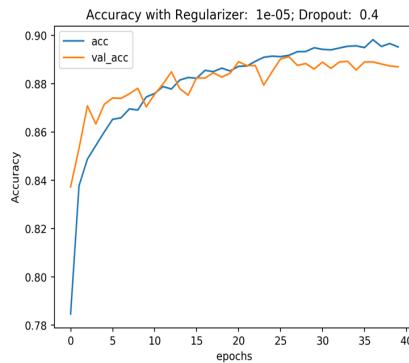

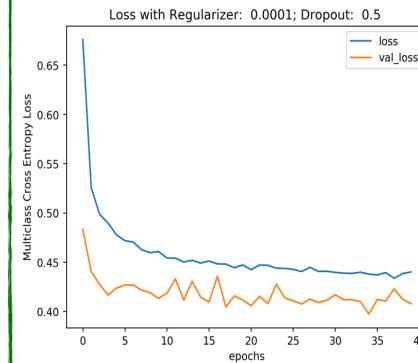

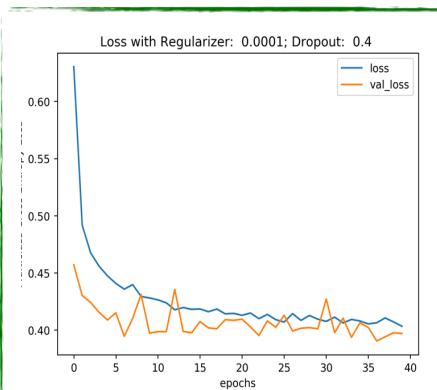

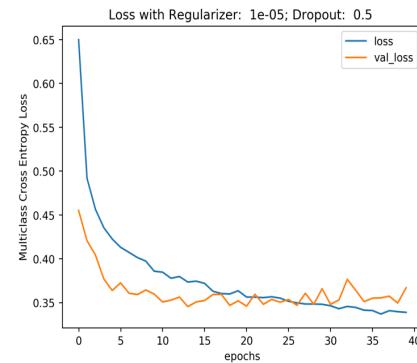

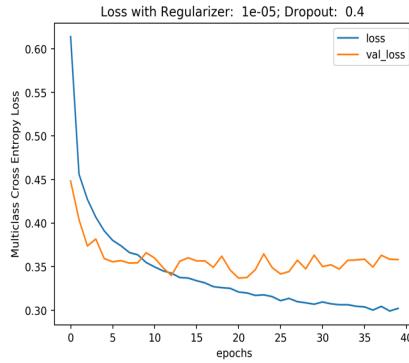

similar trend as loss

(better than L2 regularization in this case)

# DROPOUT AND L2 REGULARIZATION

best achieves test loss ~0.4, test accuracy ~ 88%

## CONCLUSIONS FROM REGULARIZATION EXPERIMENTS

Main goal of Machine Learning is to  
**GENERALIZE**

A combination of dropout and L2 regularization worked best

This required a pretty-high dropout rate plus regularization  
to not over-fit...

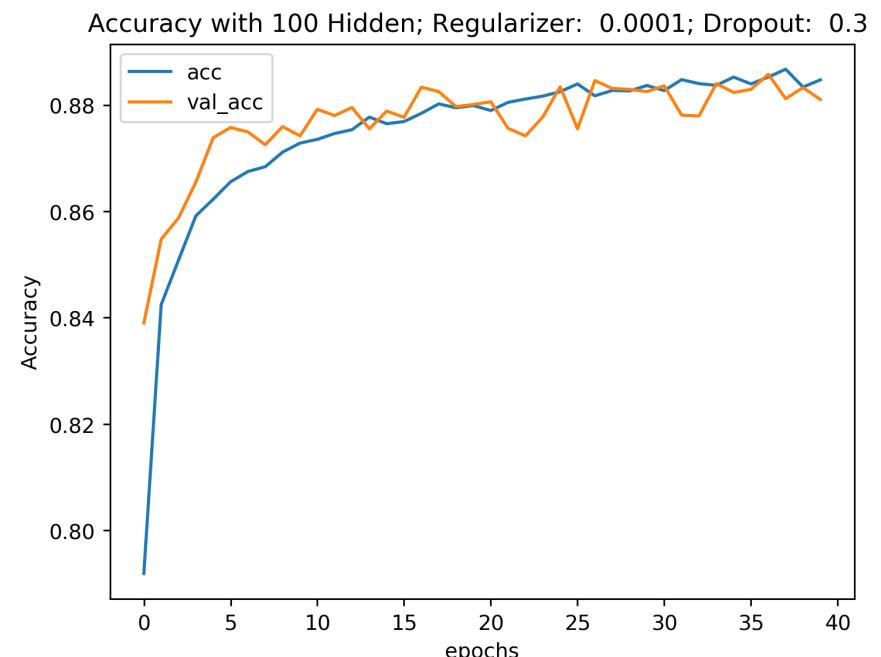

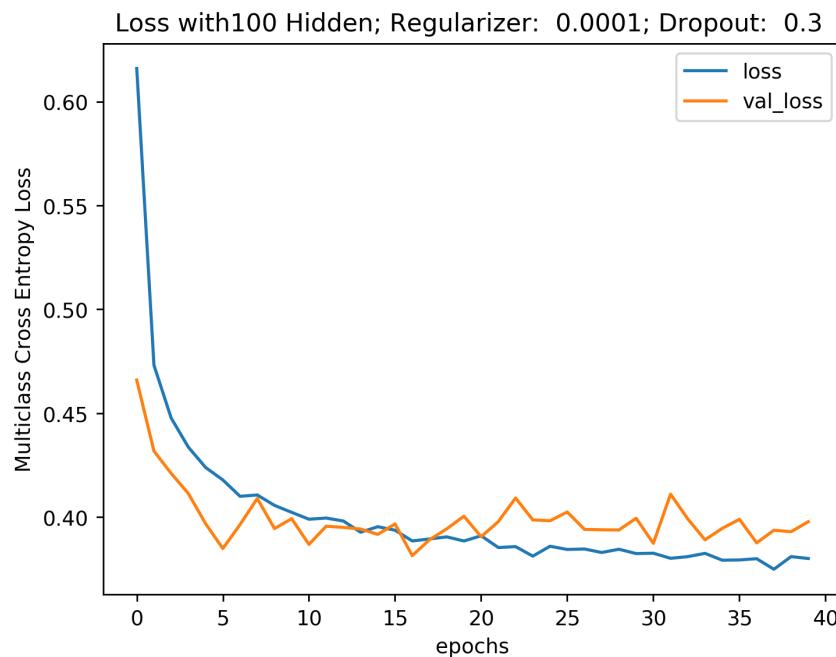

Note: we will see ~94% accuracy with CNNs on this problem

**Nominal Values:**  
dropout rate:  $\approx 20\%$   
L2 Regularization: [1e-5, 1e-3]

What does this suggest to you??

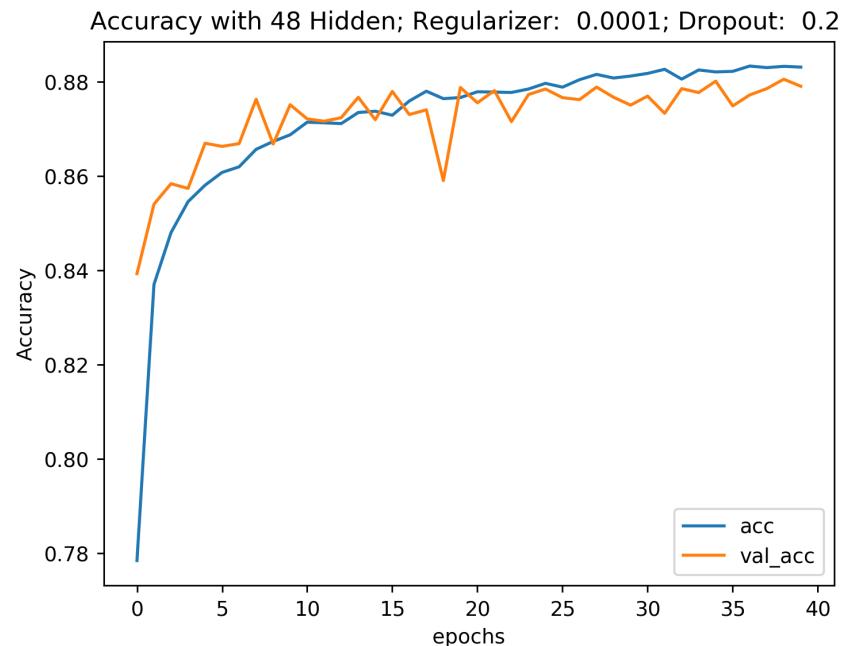

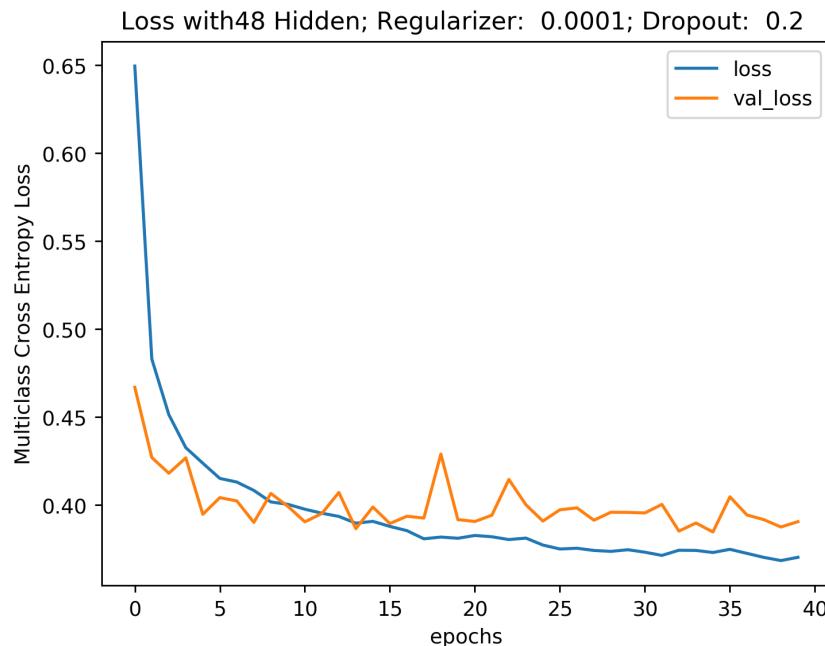

# SMALLER MODEL, LESS REGULARIZATION

results with 100 hidden neurons

# SMALLER MODEL, LESS REGULARIZATION

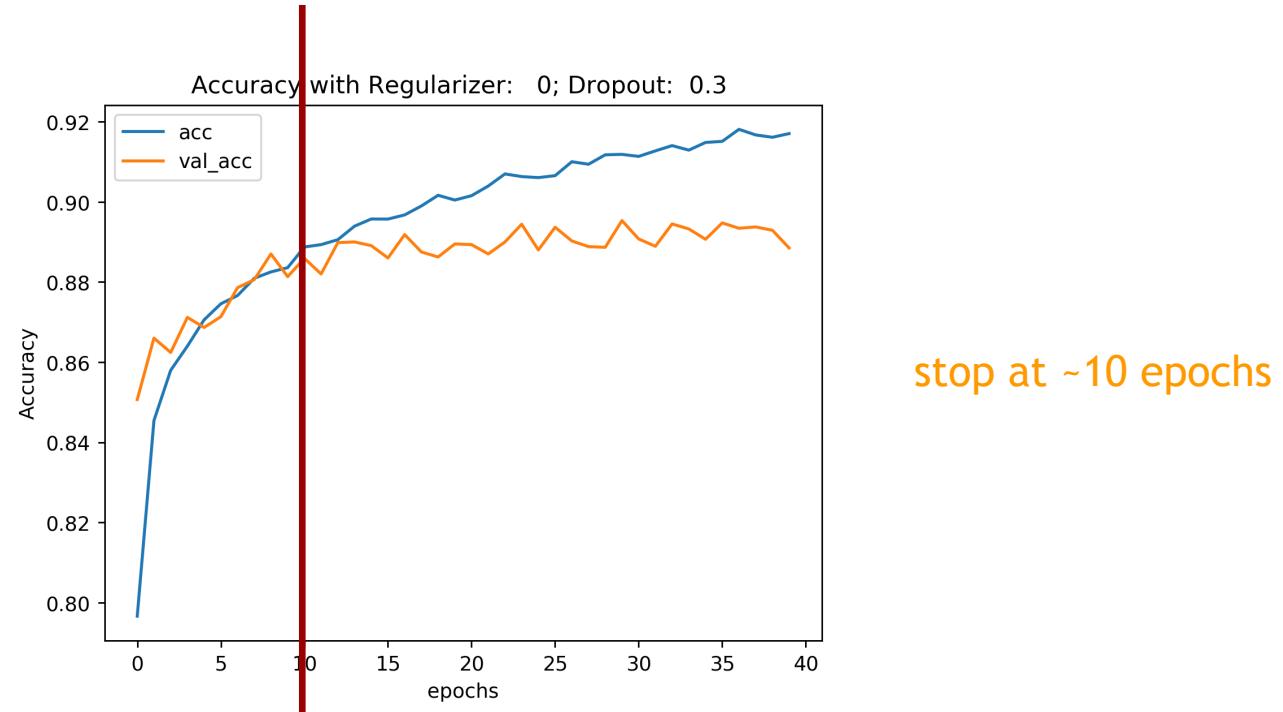

similar results with 48 hidden neurons

## ANOTHER REGULARIZATION METHOD

“early stopping”

stop training when val starts performs *consistently* better than train

# TOPIC OUTLINE

- Universal Approximation Theorem
  - Why Deep?
- A Gentle Introduction to PyTorch
- Vanishing gradient and activations
- Weight initialization
- Cost functions, regularization, dropout
- Optimizers
- Batch Normalization
- Hyperparameter optimization

# OPTIMIZERS

# OPTIMIZERS

Optimizers are **modifications** to standard  
Stochastic Gradient Descent (SGD)

Three common modifications:

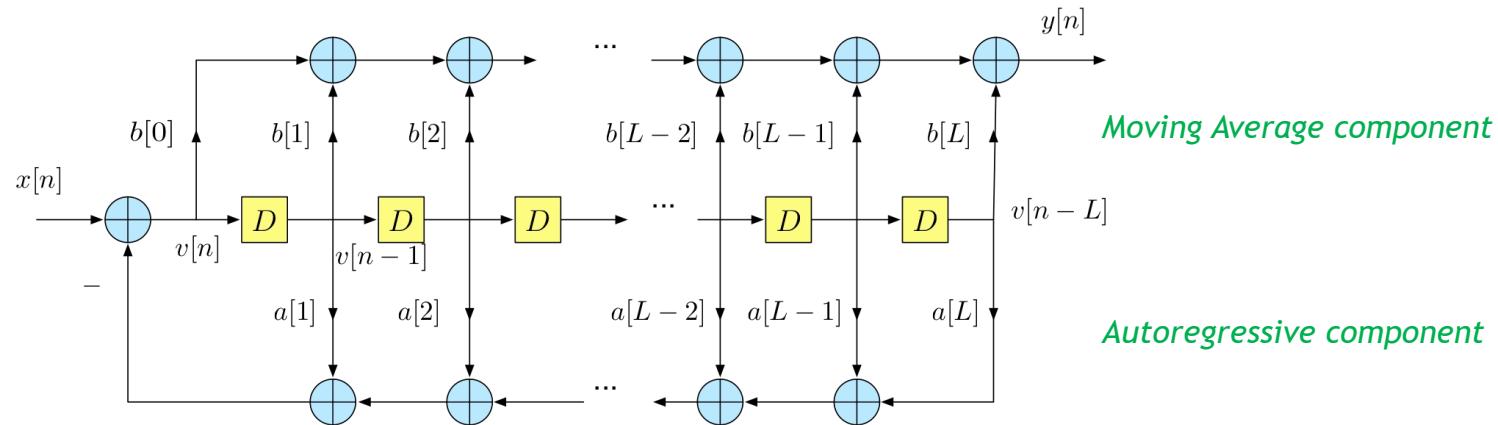

1. Gradient filtering
  2. Gradient normalization
  3. Learning rate schedule
- 
- 1 and 2 usually associated with the “optimizer”
  - learning rate schedule considered a separate parameter tuning task

# LTI FILTER REVIEW

# REVIEW OF ARMA LTI FILTERS

$$v[n] = x[n] - (a[1]v[n-1] + a[2]v[n-2] + \dots + a[L]v[n-L])$$

$$y[n] = b[0]v[n] + b[1]v[n-1] + b[2]v[n-2] + \dots + b[L]v[n-L]$$

$$\text{state}[n] = (v[n-1], v[n-2], \dots, v[n-L])$$

implements this difference equation:

$$y[n] = \sum_{i=0}^L b[i]x[n-i] - \sum_{i=1}^L a[i]y[n-i]$$

Frequency response:

$$H(z) = \frac{b[0] + b[1]z^{-1} + b[2]z^{-2} + \dots + b[L]z^{-L}}{1 + a[1]z^{-1} + a[2]z^{-2} + \dots + a[L]z^{-L}}$$

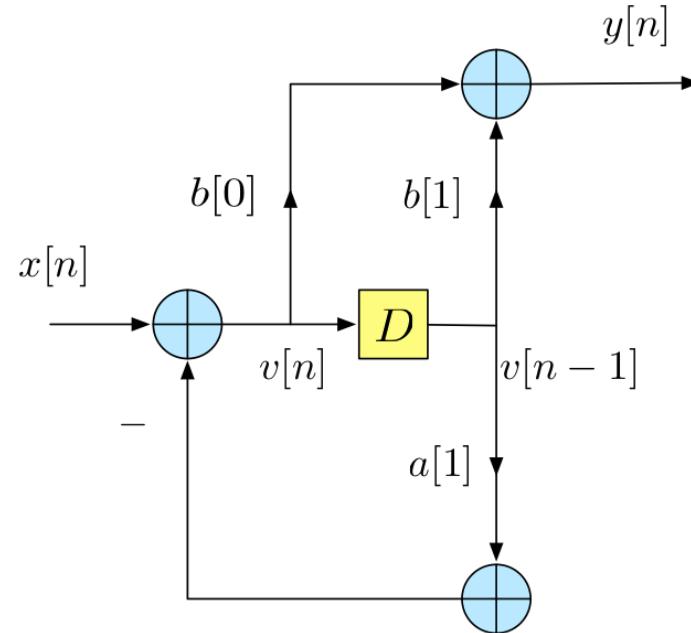

$$z = e^{j2\pi\nu}$$

**this is the canonical block diagram for an  $L$ th order filter**

## REVIEW OF ARMA LTI FILTERS

first order ARMA filter

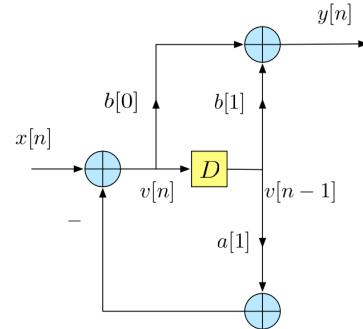

$$y[n] = -a[1]y[n - 1] + b[0]x[n] + b[1]x[n - 1]$$

$$H(z) = \frac{b[0] + b[1]z^{-1}}{1 + a[1]z^{-1}}$$

# REVIEW OF FIRST ORDER LTI FILTERS

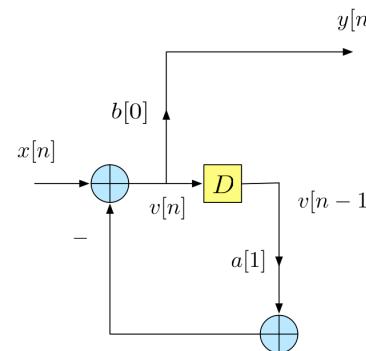

Unit DC-Gain AR1:

$$y[n] = \alpha y[n-1] + (1 - \alpha)x[n]$$

$$H(z) = \frac{(1 - \alpha)}{1 + \alpha z^{-1}}$$

has input-gain =  $(1 - \alpha)$

Unit input-Gain AR1:

$$y[n] = \alpha y[n-1] + x[n]$$

$$H(z) = \frac{1}{1 + \alpha z^{-1}}$$

has DC-gain =  $1/(1 - \alpha)$

$$y[n] = -a[1]y[n-1] + b[0]x[n]$$

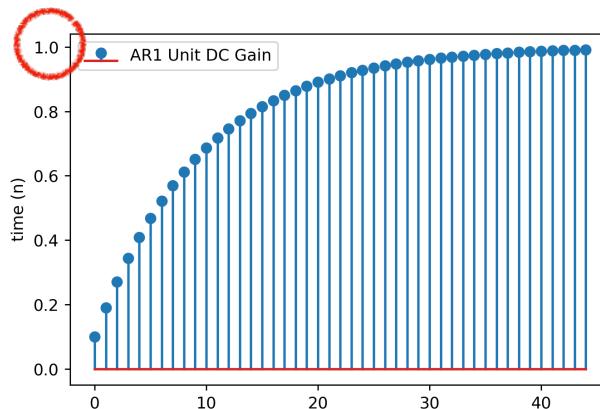

$$H(z) = \frac{b[0]}{1 + a[1]z^{-1}}$$

*Recall:* as  $\alpha$  approaches 1, the filter gains memory and behaves as low-pass

# REVIEW OF FIRST ORDER LTI FILTERS

unit step response with  $\alpha = 0.9$

special cases for AR1:

Unit DC-Gain AR1:

$$y[n] = \alpha y[n - 1] + (1 - \alpha)x[n]$$

$$s[n] = 1 - \alpha^{n+1}$$

$$H(z) = \frac{(1 - \alpha)}{1 + \alpha z^{-1}}$$

has input-gain =  $(1 - \alpha)$

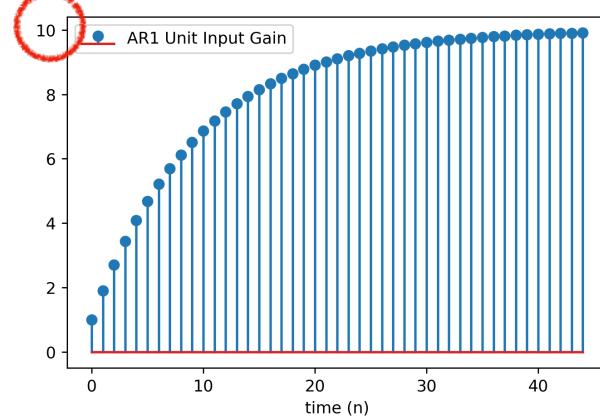

Unit input-Gain AR1:

$$y[n] = \alpha y[n - 1] + x[n]$$

$$s[n] = \frac{1 - \alpha^{n+1}}{1 - \alpha}$$

$$H(z) = \frac{1}{1 + \alpha z^{-1}}$$

has DC-gain =  $1/(1 - \alpha)$

*Recall:* as  $\alpha$  approaches 1, the filter gains memory and behaves as low-pass

# TRANSIENT COMPENSATION

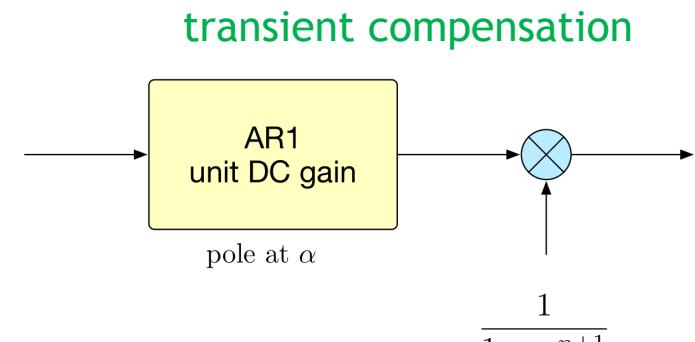

**Unit DC Gain AR1:** transient to reach steady state DC response

**Unit input Gain AR1:** pole dependent DC gain

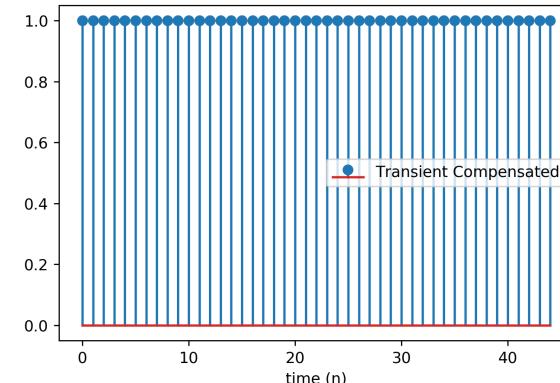

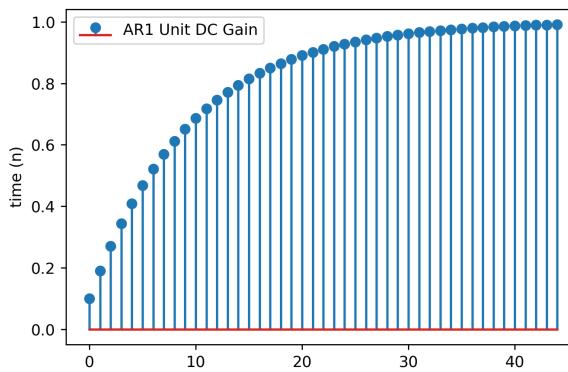

$$y[n] = \alpha y[n - 1] + (1 - \alpha)x[n]$$

$$H(z) = \frac{(1 - \alpha)}{1 - \alpha z^{-1}}$$

$$s[n] = 1 - \alpha^{n+1}$$

**transient compensated step response**

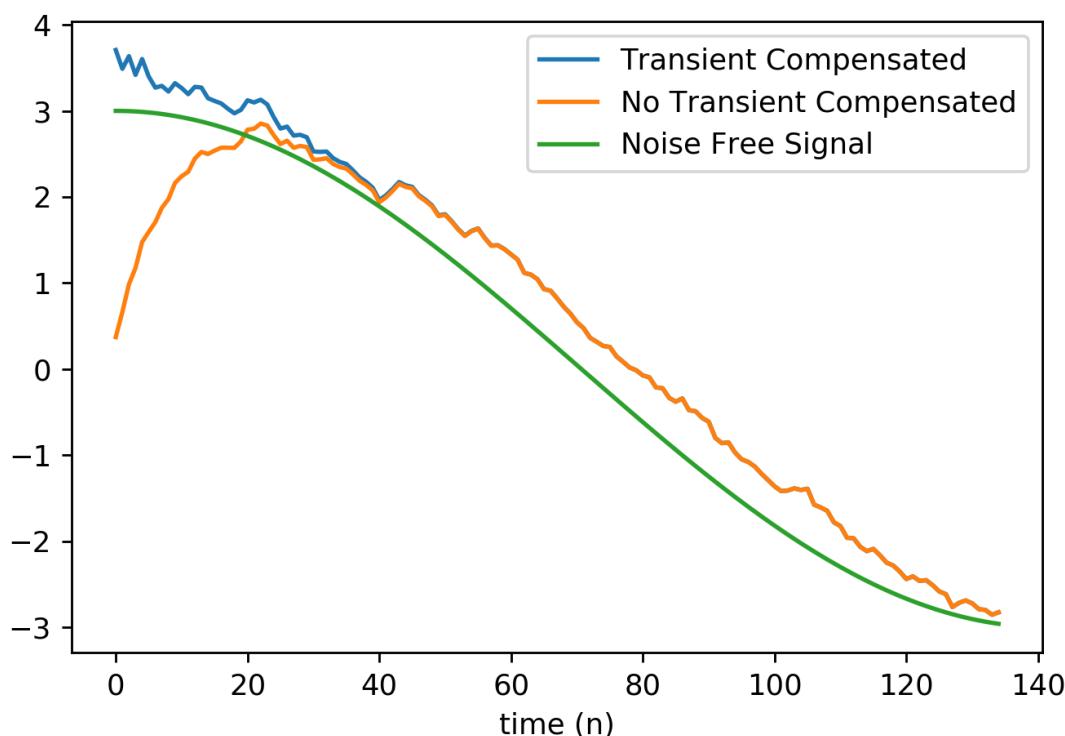

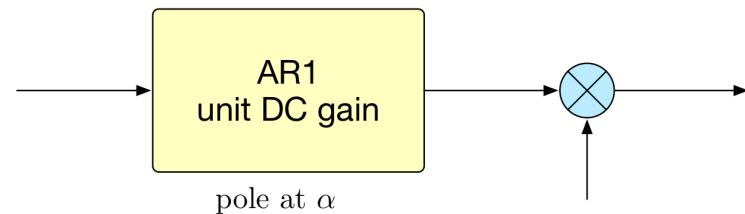

works for any scaled  
step input!

# TRANSIENT COMPENSATION - NOISY EXAMPLE

Transient compensation

this example is a cosine in noise  
( $\alpha = 0.9$ )

nice signal processing idea  
(comes from deep learning AFAIK)

# DEEP-LEARNING OPTIMIZERS

# SUMMARY OF OPTIMIZERS

	gradient filtering	gradient normalization	grad variance filter	learning rate schedule	
	SGD	none	none	n/a	separate
SGD w/ momentum		AR1, unit input gain	none	n/a	separate

RMSprop		none	yes	AR1, unit DC gain	separate, but gradient norm does alter
Adam		AR1, unit input gain, transient compensation	yes	AR1, unit input gain, transient compensation	separate, but gradient norm does alter
Nadam (Adam w/ Nesterov)		ARMA1, transient compensation	yes	ARMA1, transient compensation	separate, but gradient norm does alter

# GRADIENT FILTERING

# GENERAL OPTIMIZER STRUCTURE + SGD

parameter update:

$$\theta[i] = \theta[i - 1] + \Delta[i]$$

$i \sim$  indexes parameter updates  
(i.e., mini-batch)

input step/gradient (update):

$$\nabla[i] = \frac{\partial C}{\partial \theta[i - 1]}$$

$$g[i] = -\eta \frac{\partial C}{\partial \theta[i - 1]}$$

SGD:

$$\Delta[i] = g[i]$$

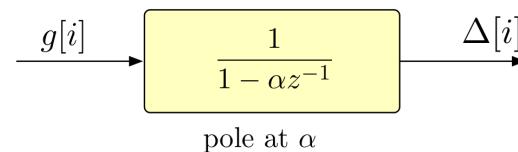

SGD with momentum:

$$v[i] = \alpha v[i - 1] + g[i]$$

$$\Delta[i] = v[i]$$

$v$  is called the “velocity”

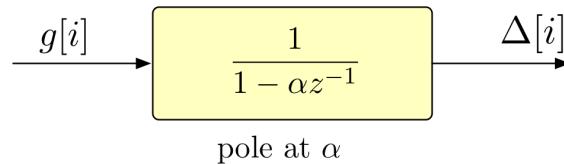

$\alpha$  is called “momentum”  
( $\alpha \sim 0.9$ )

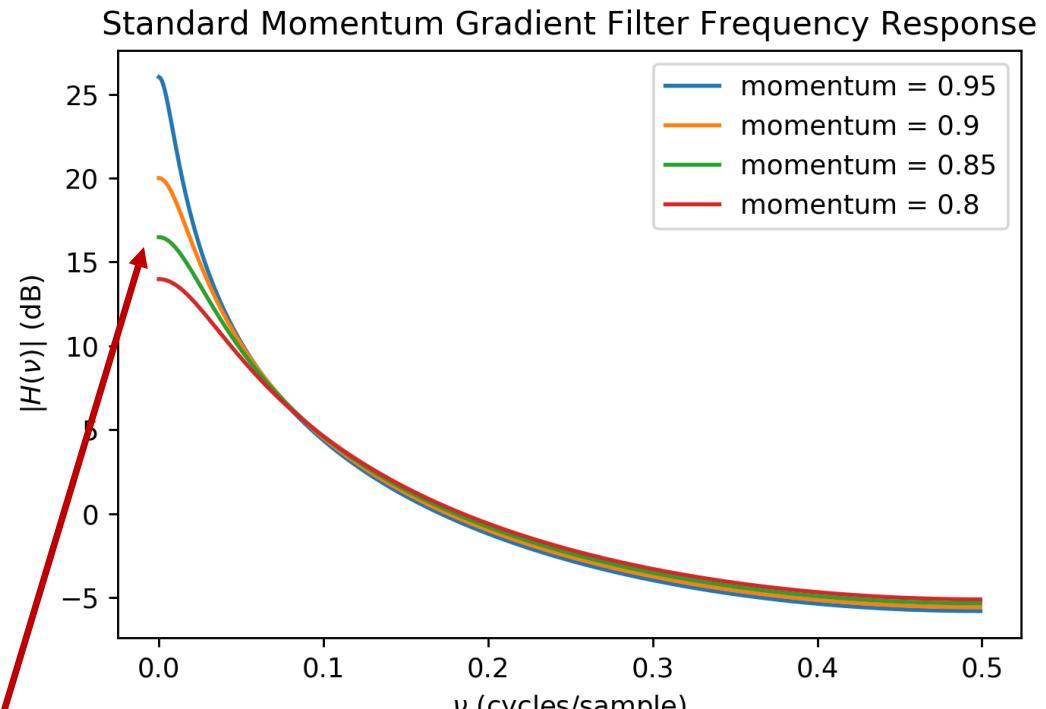

Momentum: low-pass filter on gradient –  
removes high-frequency gradient noise

## “STANDARD” MOMENTUM

Momentum: low-pass filter on the gradient removes high-frequency gradient noise

note that your momentum and learning rate are coupled

choosing larger momentum effectively increases your learning rate

## SGD WITH NESTEROV MOMENTUM

parameter update:

$$\theta[i] = \theta[i - 1] + \Delta[i]$$

input step/gradient (update):

$$\nabla[i] = \frac{\partial C}{\partial \theta[i - 1]} \quad g[i] = -\eta \frac{\partial C}{\partial \theta[i - 1]}$$

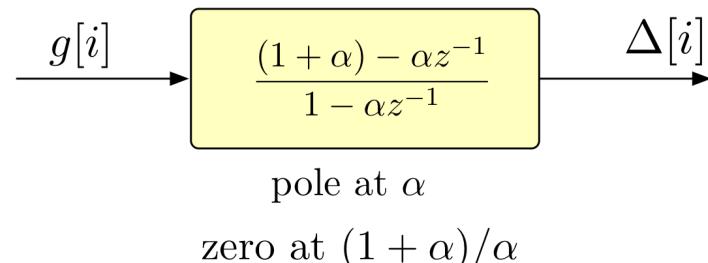

$$v[i] = \alpha v[i - 1] + g[i]$$

*v* is called the “velocity”

$$\Delta[i] = (1 + \alpha)v[i] - \alpha v[i - 1]$$

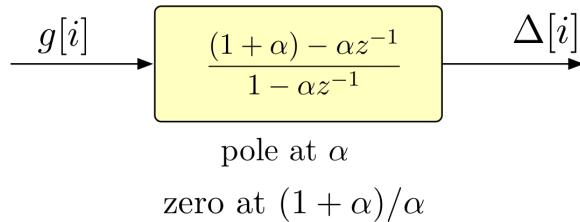

*α* is called “momentum”

( $\alpha \sim 0.9$ )

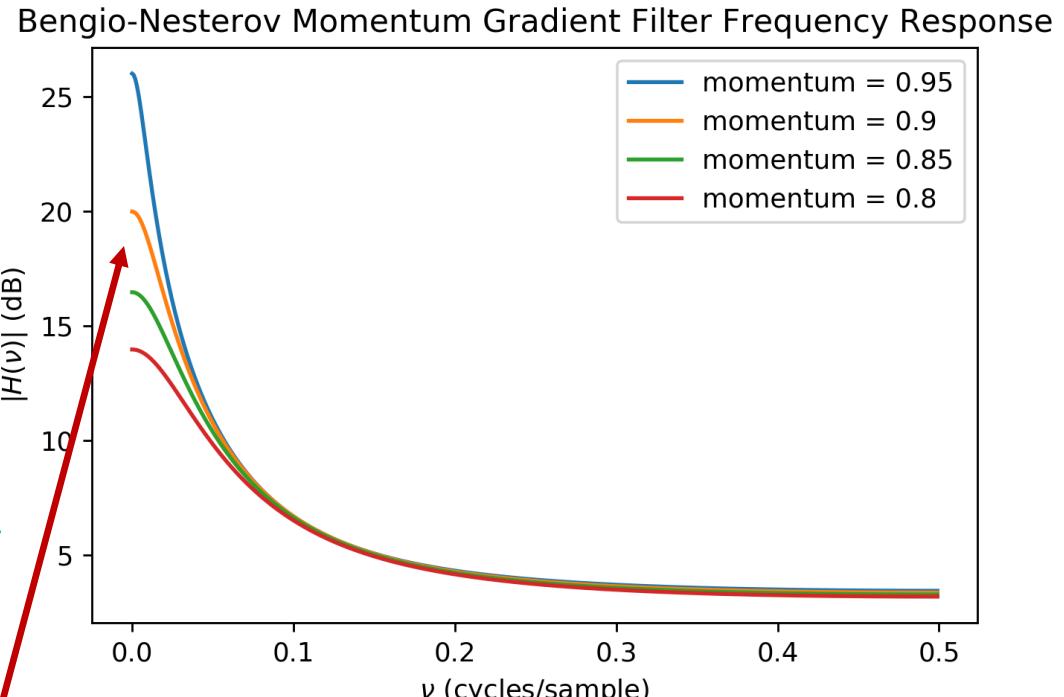

## SGD WITH NESTEROV MOMENTUM

Momentum: low-pass filter on the gradient removes high-frequency gradient noise

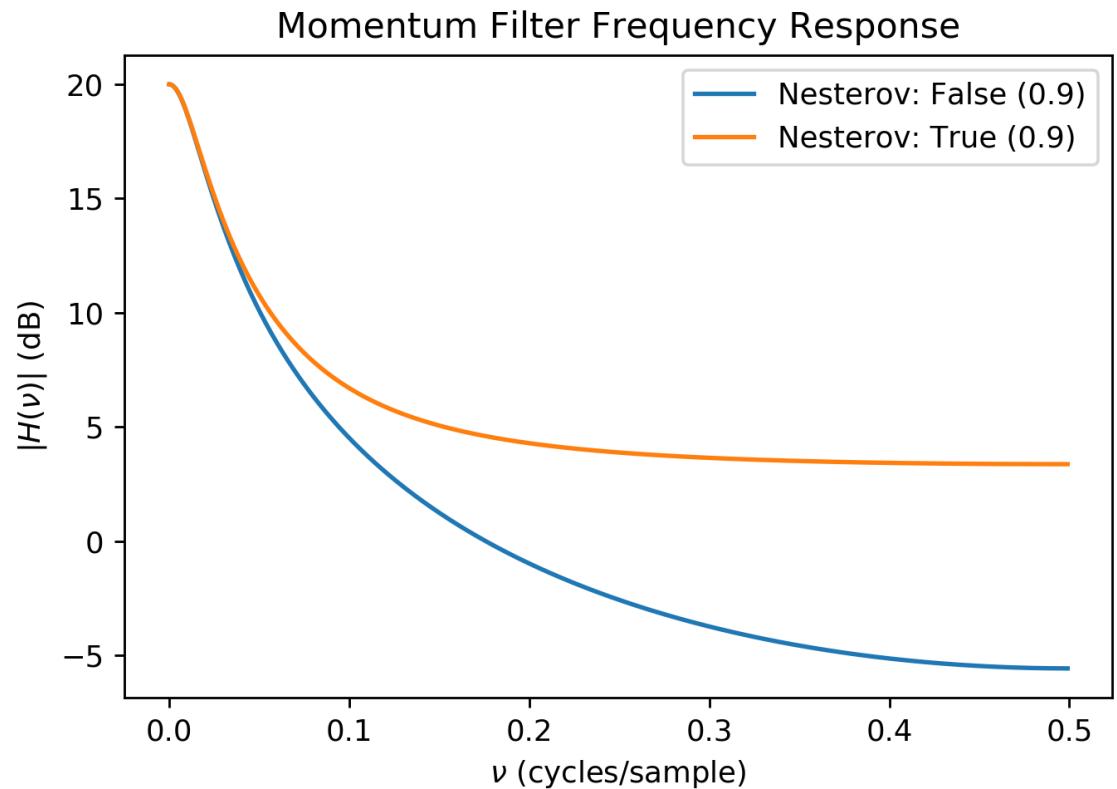

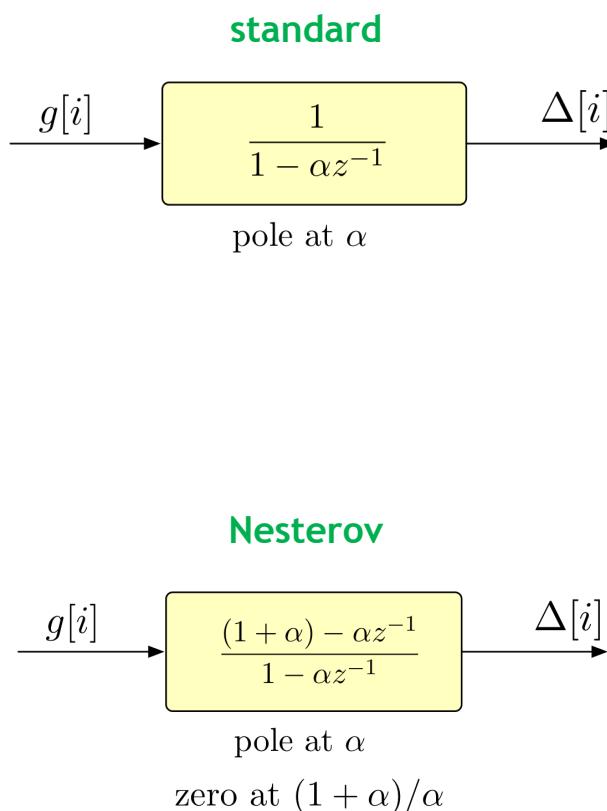

note that your momentum and learning rate are coupled

choosing larger momentum effectively increases your learning rate

# STANDARD MOMENTUM VS NESTEROV MOMENTUM

**standard** momentum attenuates high frequencies  
more than Nesterov momentum

## NESTEROV MOMENTUM (TYPICAL MOTIVATION)

Motivated as compute “preliminary” parameter update before updating velocity and then adjust for velocity update

$$v_t = \mu_{t-1} v_{t-1} - \boxed{\epsilon_{t-1} \nabla f(\theta_{t-1} + \mu_{t-1} v_{t-1})}$$

$$\theta_t = \theta_{t-1} + v_t$$

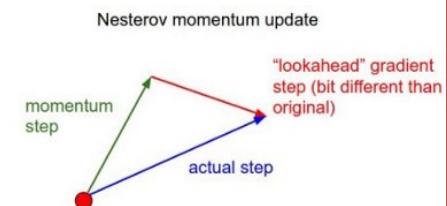

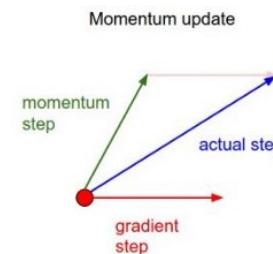

what exactly is this?  
... it's the *post-update* value

$$v_t = \mu_{t-1} v_{t-1} - \epsilon_{t-1} \nabla f(\Theta_{t-1})$$

$$\Theta_t = \Theta_{t-1} - \mu_{t-1} v_{t-1} + \mu_t v_t + v_t$$

$$= \Theta_{t-1} + \mu_t \mu_{t-1} v_{t-1} + (1 + \mu_t) \epsilon_{t-1} \nabla f(\Theta_{t-1})$$

typical explanation

“Bengio’s Formulation”

This is what PyTorch does!

**Effect:** adjust momentum coefficient invariant to learning rate

Bengio, Yoshua, Nicolas Boulanger-Lewandowski, and Razvan Pascanu. "Advances in optimizing recurrent networks." 2013 IEEE International Conference on Acoustics, Speech and Signal Processing. IEEE, 2013.

# NESTEROV MOMENTUM

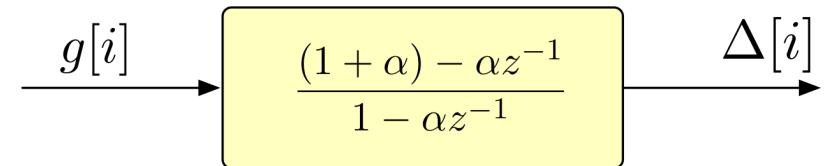

“Bengio’s Formulation”

$$v[i] = \alpha v[i - 1] + g[i]$$

$$\theta[i] = \theta[i - 1] + (1 + \alpha)v[i] - \alpha v[i - 1]$$

$$\Delta[i] = (1 + \alpha)v[i] - \alpha v[i - 1]$$

$$= v[i] + \underbrace{\alpha(v[i] - v[i - 1])}_{\text{acceleration}}$$

pole at  $\alpha$

zero at  $(1 + \alpha)/\alpha$

this formulation makes the pattern clear: choose any low-pass filter for this task – *i.e.*, optimize a second order ARMA filter (*e.g.*, Butterworth)

# GRADIENT NORMALIZATION

## GRADIENT NORMALIZATION

Idea: estimate gradient RMS and normalize

parameter update:

$$\theta[i] = \theta[i - 1] + \Delta[i]$$

input step/gradient (update):

$$\nabla[i] = \frac{\partial C}{\partial \theta[i - 1]} \quad g[i] = -\eta \frac{\partial C}{\partial \theta[i - 1]}$$

Can compute the RMS value of

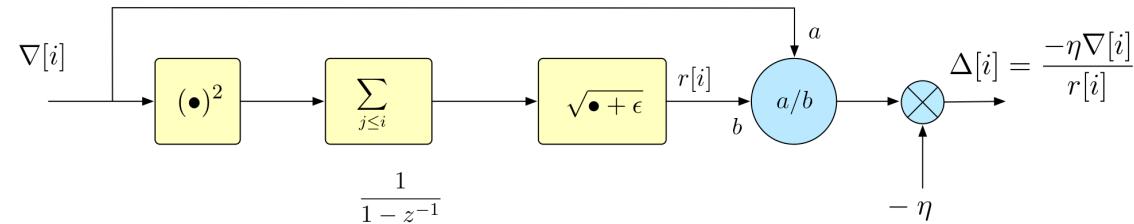

$$\nabla[i] \quad \text{or} \quad g[i]$$

this is done by using a low-pass filter on the square of these quantities  
– i.e., like computing the sample second moment

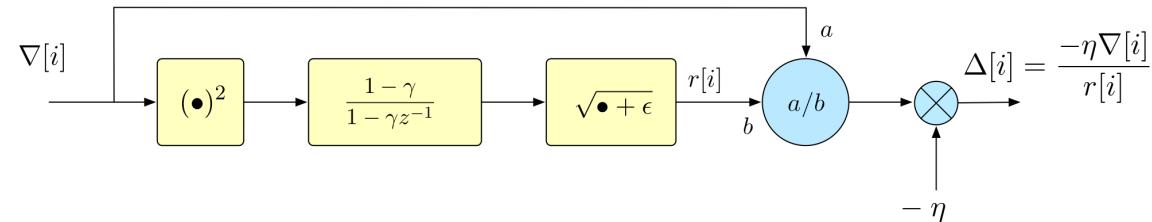

# GRADIENT NORMALIZATION EXAMPLES

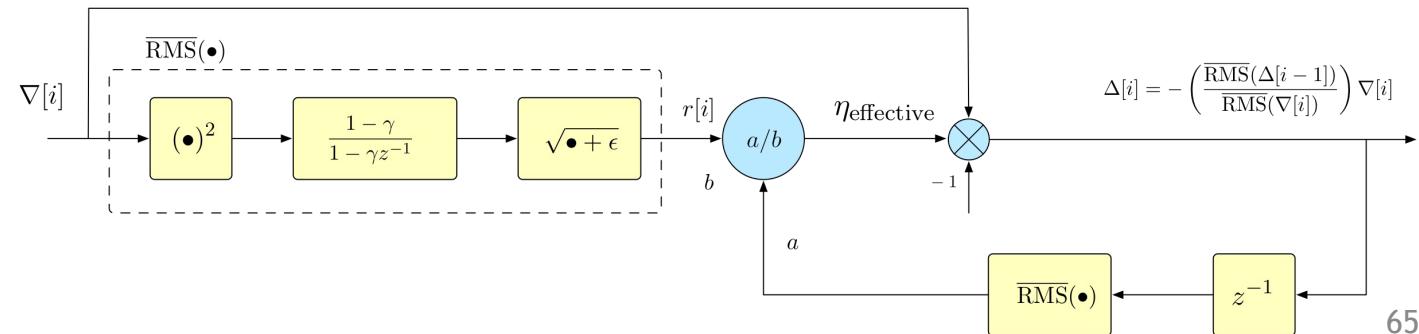

**Adagrad:**

**RMSprop:**

**Adadelta:**

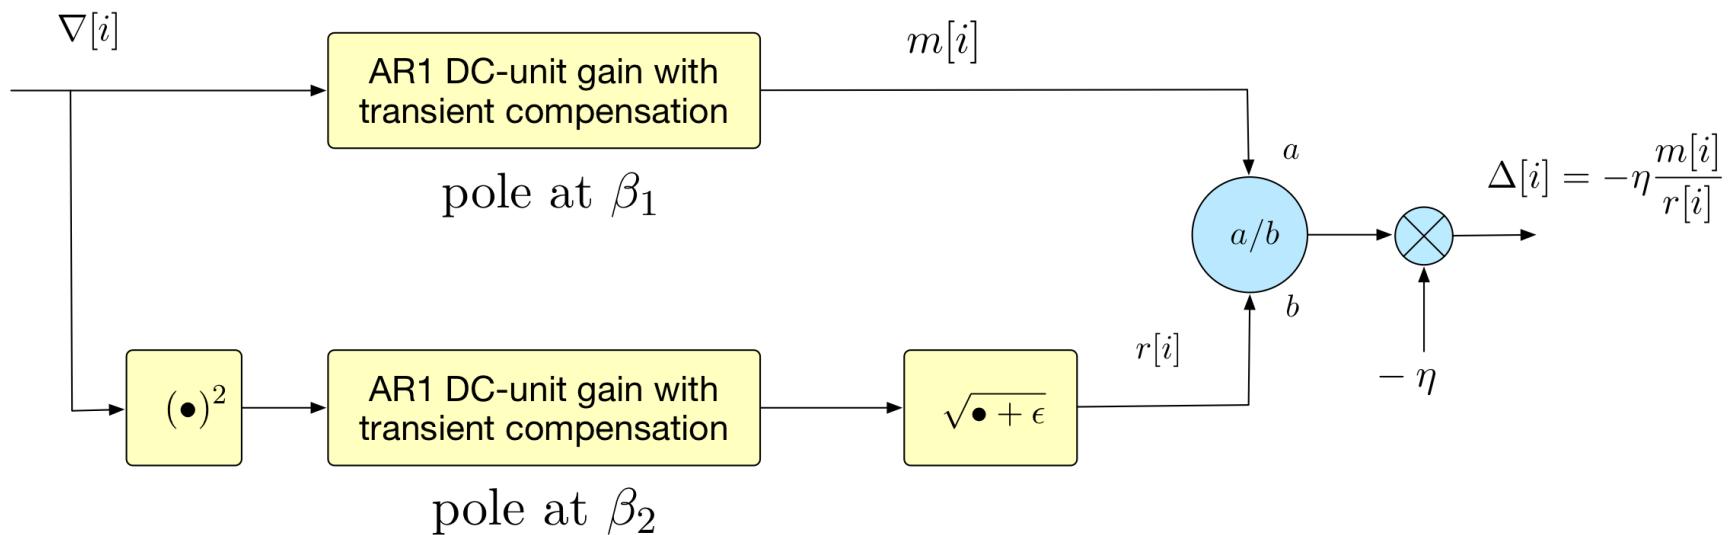

## ADAM (THE BEST OF ALL WORLDS?)

use unit-DC gain filters for gradient filtering and for computing the second moment

use transient compensation to reduce start-up effects of filters

# ADAM IMPLEMENTATION

---

**Algorithm 1:** *Adam*, our proposed algorithm for stochastic optimization. See section 2 for details, and for a slightly more efficient (but less clear) order of computation.  $g_t^2$  indicates the elementwise square  $g_t \odot g_t$ . Good default settings for the tested machine learning problems are  $\alpha = 0.001$ ,  $\beta_1 = 0.9$ ,  $\beta_2 = 0.999$  and  $\epsilon = 10^{-8}$ . All operations on vectors are element-wise. With  $\beta_1^t$  and  $\beta_2^t$  we denote  $\beta_1$  and  $\beta_2$  to the power  $t$ .

---

**Require:**  $\alpha$ : Stepsize  
**Require:**  $\beta_1, \beta_2 \in [0, 1]$ : Exponential decay rates for the moment estimates  
**Require:**  $f(\theta)$ : Stochastic objective function with parameters  $\theta$   
**Require:**  $\theta_0$ : Initial parameter vector

$m_0 \leftarrow 0$  (Initialize 1<sup>st</sup> moment vector)  
 $v_0 \leftarrow 0$  (Initialize 2<sup>nd</sup> moment vector)  
 $t \leftarrow 0$  (Initialize timestep)

**while**  $\theta_t$  not converged **do**

- $t \leftarrow t + 1$
- $g_t \leftarrow \nabla_{\theta} f_t(\theta_{t-1})$  (Get gradients w.r.t. stochastic objective at timestep  $t$ )
- $m_t \leftarrow \beta_1 \cdot m_{t-1} + (1 - \beta_1) \cdot g_t$  (Update biased first moment estimate)
- $v_t \leftarrow \beta_2 \cdot v_{t-1} + (1 - \beta_2) \cdot g_t^2$  (Update biased second raw moment estimate)
- $\hat{m}_t \leftarrow m_t / (1 - \beta_1^t)$  (Compute bias-corrected first moment estimate)
- $\hat{v}_t \leftarrow v_t / (1 - \beta_2^t)$  (Compute bias-corrected second raw moment estimate)
- $\theta_t \leftarrow \theta_{t-1} - \alpha \cdot \hat{m}_t / (\sqrt{\hat{v}_t} + \epsilon)$  (Update parameters)

**end while**

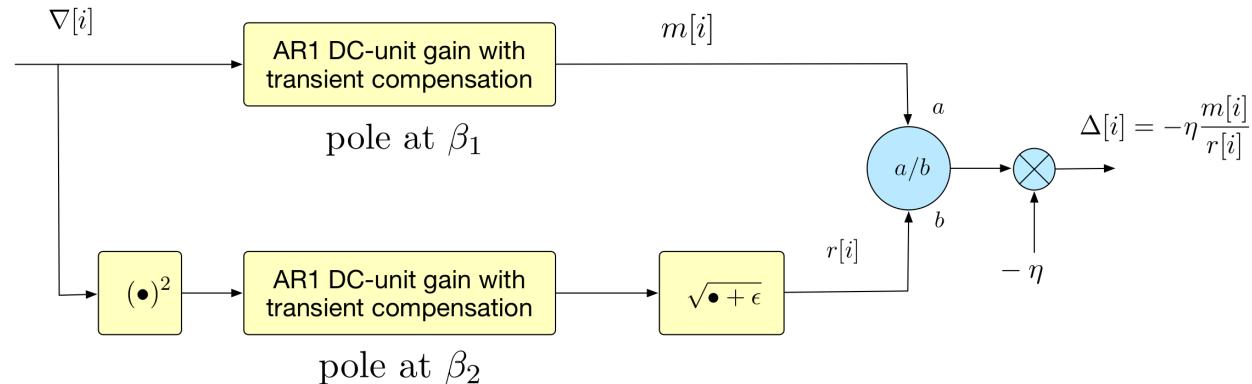

**return**  $\theta_t$  (Resulting parameters)

---

# ADAM IN PYTORCH

<https://pytorch.org/docs/stable/optim.html#torch.optim.Adam>

## Default:

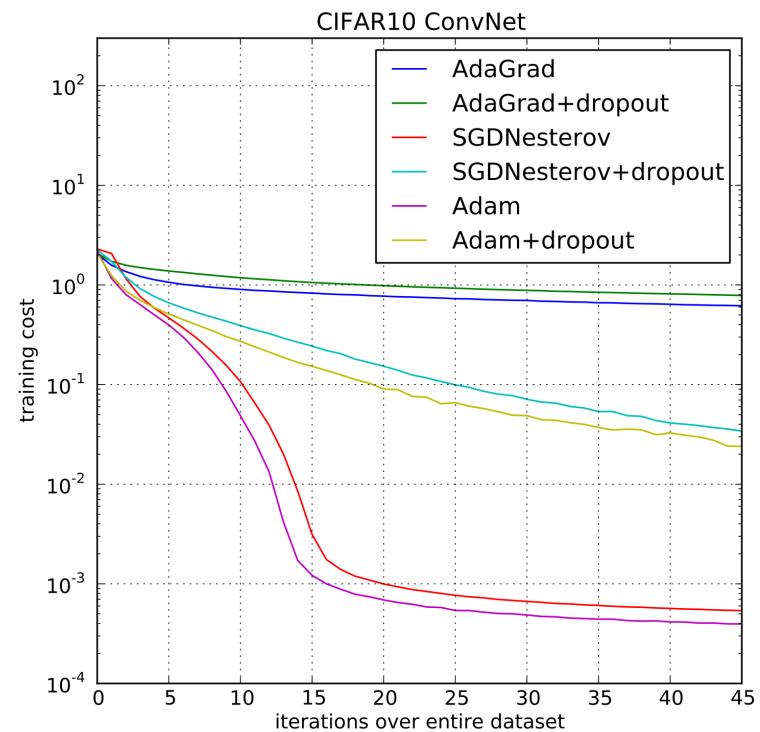

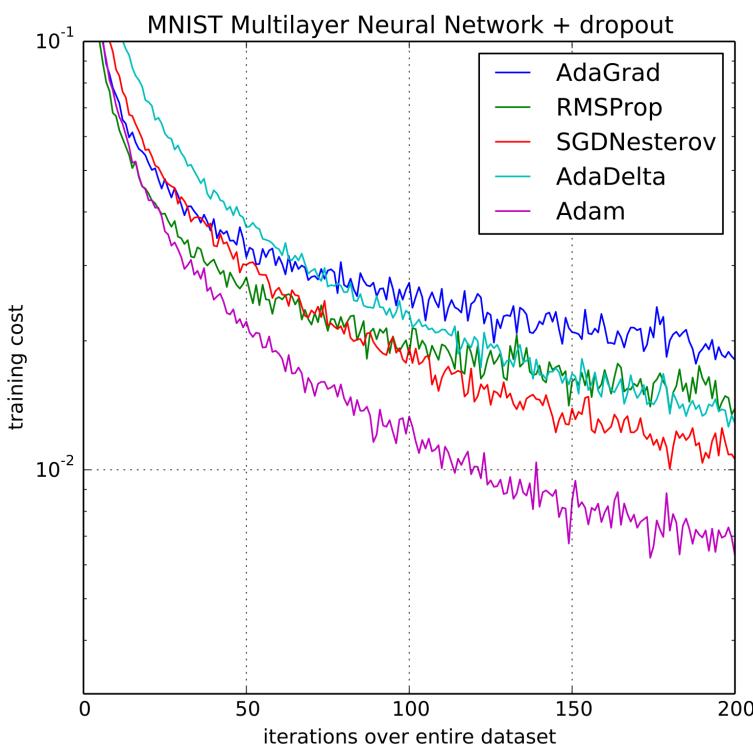

```
def __init__(self, params, lr=1e-3, betas=(0.9, 0.999), eps=1e-8,
            weight_decay=0, amsgrad=False):
```

## Tuned:

```
my_adam = optim.Adam(lr=0.002, betas=(0.92, 0.99),
                      eps=1e-09)
```

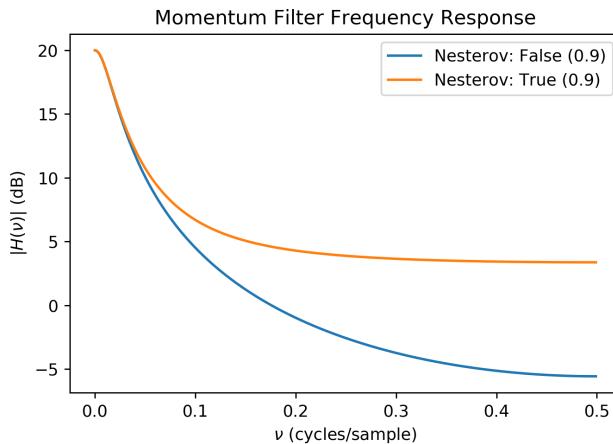

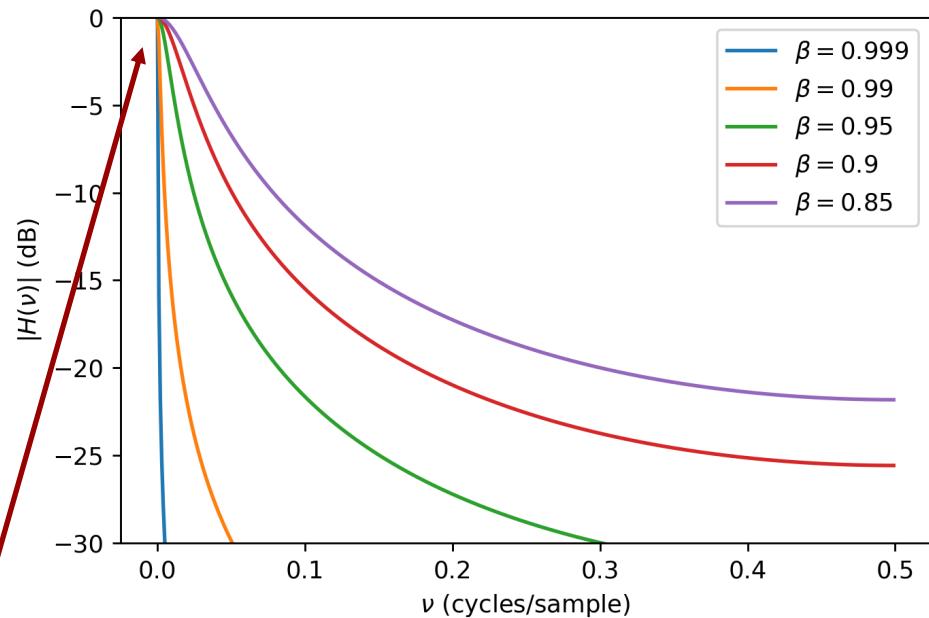

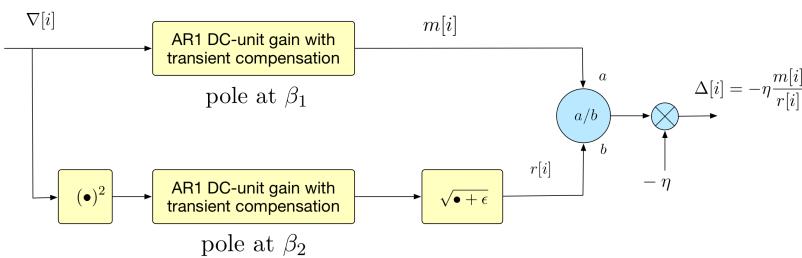

# ADAM PERFORMANCE

# ADAM GRADIENT FILTER FREQUENCY RESPONSE

no coupling between momentum and learning rate!

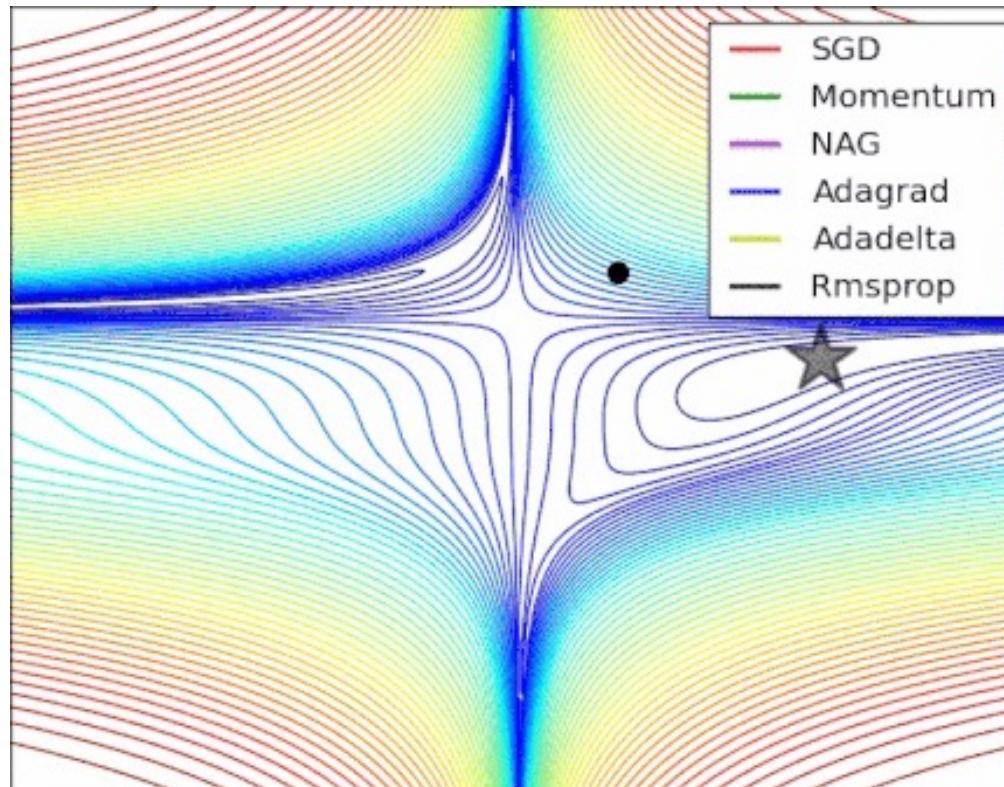

# SUMMARY OF OPTIMIZERS

	gradient filtering	gradient normalization	grad variance filter	learning rate schedule	
	SGD	none	none	n/a	separate
SGD w/ momentum		AR1, unit input gain	none	n/a	separate
SGD w/ Nesterov Momentum		ARMA1 (1 pole, 1 zero)	none	n/a	separate
Adagrad		none	yes	summer	separate, but gradient norm does alter
Adadelta		none	yes	AR1, unit DC gain	separate, but gradient norm does alter
RMSprop		none	yes	AR1, unit DC gain	separate, but gradient norm does alter
Adam		AR1, unit input gain, transient compensation	yes	AR1, unit input gain, transient compensation	separate, but gradient norm does alter
Nadam (Adam w/ Nesterov)		ARMA1, transient compensation	yes	ARMA1, transient compensation	separate, but gradient norm does alter

# LEARNING RATE SCHEDULERS

## LEARNING RATE SCHEDULES

Change (typically decrease) the learning rate as we do more parameter updates (batches)

Recall LMS: large learning rate implies faster convergences, but more “maladjustment error” (*i.e.*, *gradient noise*)

Could also use a LR schedule to try to force the optimizer out of a local minimum

(to go to a better local minimum, likely)

# LEARNING RATE SCHEDULES IN PYTORCH

<https://pytorch.org/docs/stable/optim.html#how-to-adjust-learning-rate>

```
1 learning_rate = 0.1
2
3 optimizer = torch.optim.SGD(model.parameters(), lr=learning_rate, momentum=0.9, nesterov=True)
4
5 # step_size: at how many multiples of epoch you decay
6 # step_size = 1, after every 1 epoch, new_lr = lr*gamma
7 # step_size = 2, after every 2 epoch, new_lr = lr*gamma
8
9 # gamma = decaying factor
10 scheduler = StepLR(optimizer, step_size=1, gamma=0.1)
11
12 for epoch in range(num_epochs):
13     [...]
14     # Decay Learning Rate
15     scheduler.step()
16     # Print Learning Rate
17     print('Epoch:', epoch, 'LR:', scheduler.get_lr())
```

**Rule: apply learning rate scheduling  
AFTER optimizer update**

From LMS, we know that large learning rate implies faster convergences,  
but more “maladjustment error” (i.e., gradient noise)

```
>>> scheduler = ...
>>> for epoch in range(100):
>>>     train(...)
>>>     validate(...)
>>>     scheduler.step()
```

## COMMON LR SCHEDULES

$$\eta_i = \rho \eta_0$$

Exponential Decay

$$\eta_i = \eta_0 \left(1 - \frac{i}{N_{\text{epochs}}}\right)$$

Linear Decay

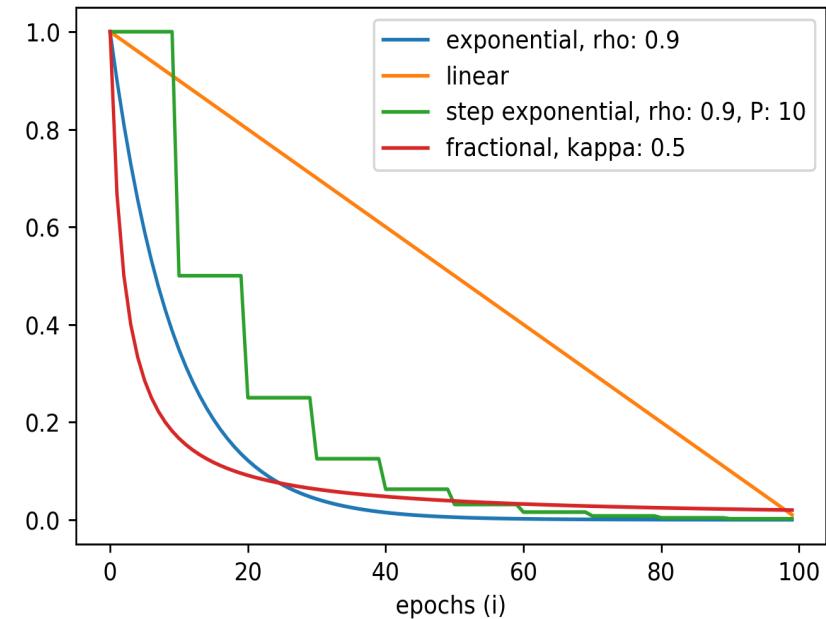

$$\eta_i = \eta_0 \rho^{[i/P]}$$

Step Exponential Decay

$$\eta_i = \frac{\eta_0}{1 + \kappa i}$$

Fractional Decay

$$0 \leq \rho \leq 1 \quad \kappa > 0$$

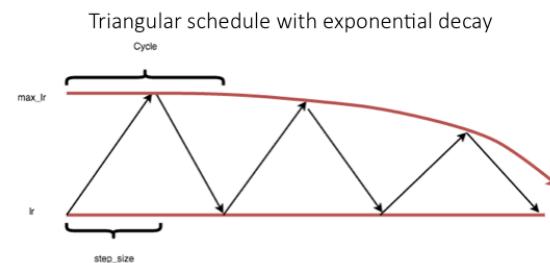

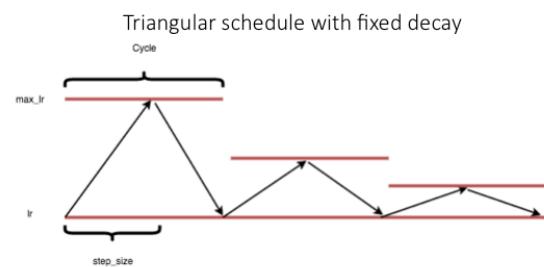

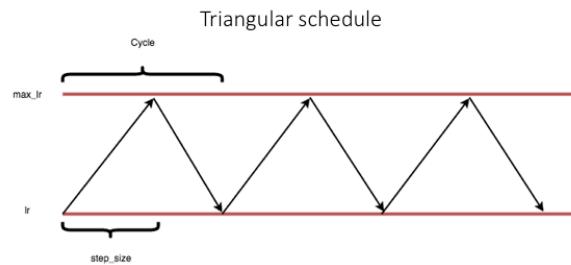

Another common LR schedule is to decrease the LR at specific epochs in a stepwise manner

e.g., every 10 epochs:  $\eta \leftarrow 0.1 \cdot \eta$

# EXOTIC “ANNEALING” LR SCHEDULES

## Triangular Schedules

## Cosine Schedules

$$\eta_t = \eta_{\min}^i + \frac{1}{2}(\eta_{\min}^i - \eta_{\max}^i) \left( 1 + \cos \left( \frac{T_{cur}}{T_i} \pi \right) \right)$$

Loshchilov, Ilya, and Frank Hutter. “SGDR: Stochastic gradient descent with warm restarts.” arXiv preprint arXiv:1608.03983 (2016).

## cosine annealing schedule in PyTorch

# BATCH NORMALIZATION

# BATCH NORMALIZATION LAYER

learn the best “level” for internal activations

**Input:** Values of  $x$  over a mini-batch:  $\mathcal{B} = \{x_1 \dots m\}$ ;  
 Parameters to be learned:  $\gamma, \beta$

**Output:**  $\{y_i = \text{BN}_{\gamma, \beta}(x_i)\}$

$$\begin{aligned}\mu_{\mathcal{B}} &\leftarrow \frac{1}{m} \sum_{i=1}^m x_i && // \text{mini-batch mean} \\ \sigma_{\mathcal{B}}^2 &\leftarrow \frac{1}{m} \sum_{i=1}^m (x_i - \mu_{\mathcal{B}})^2 && // \text{mini-batch variance} \\ \hat{x}_i &\leftarrow \frac{x_i - \mu_{\mathcal{B}}}{\sqrt{\sigma_{\mathcal{B}}^2 + \epsilon}} && // \text{normalize} \\ y_i &\leftarrow \gamma \hat{x}_i + \beta \equiv \text{BN}_{\gamma, \beta}(x_i) && // \text{scale and shift}\end{aligned}$$

**Algorithm 1:** Batch Normalizing Transform, applied to activation  $x$  over a mini-batch.

$\gamma$  and  $\beta$  are trainable parameters

this normalization is done for each mini-batch  
 but what to do when using trained network for inference?

During inference, replace the mini-batch data-average mean and variance by the data-average mean and variance over the entire dataset

11: In  $N_{\text{BN}}^{\text{inf}}$ , replace the transform  $y = \text{BN}_{\gamma, \beta}(x)$  with  
 $y = \frac{\gamma}{\sqrt{\text{Var}[x] + \epsilon}} \cdot x + \left(\beta - \frac{\gamma \mathbb{E}[x]}{\sqrt{\text{Var}[x] + \epsilon}}\right)$

commonly used and effective technique in deep CNNs

# HYPERPARAMETER OPTIMIZATION

# THIS IS HOPELESSLY COMPLEX!?!?

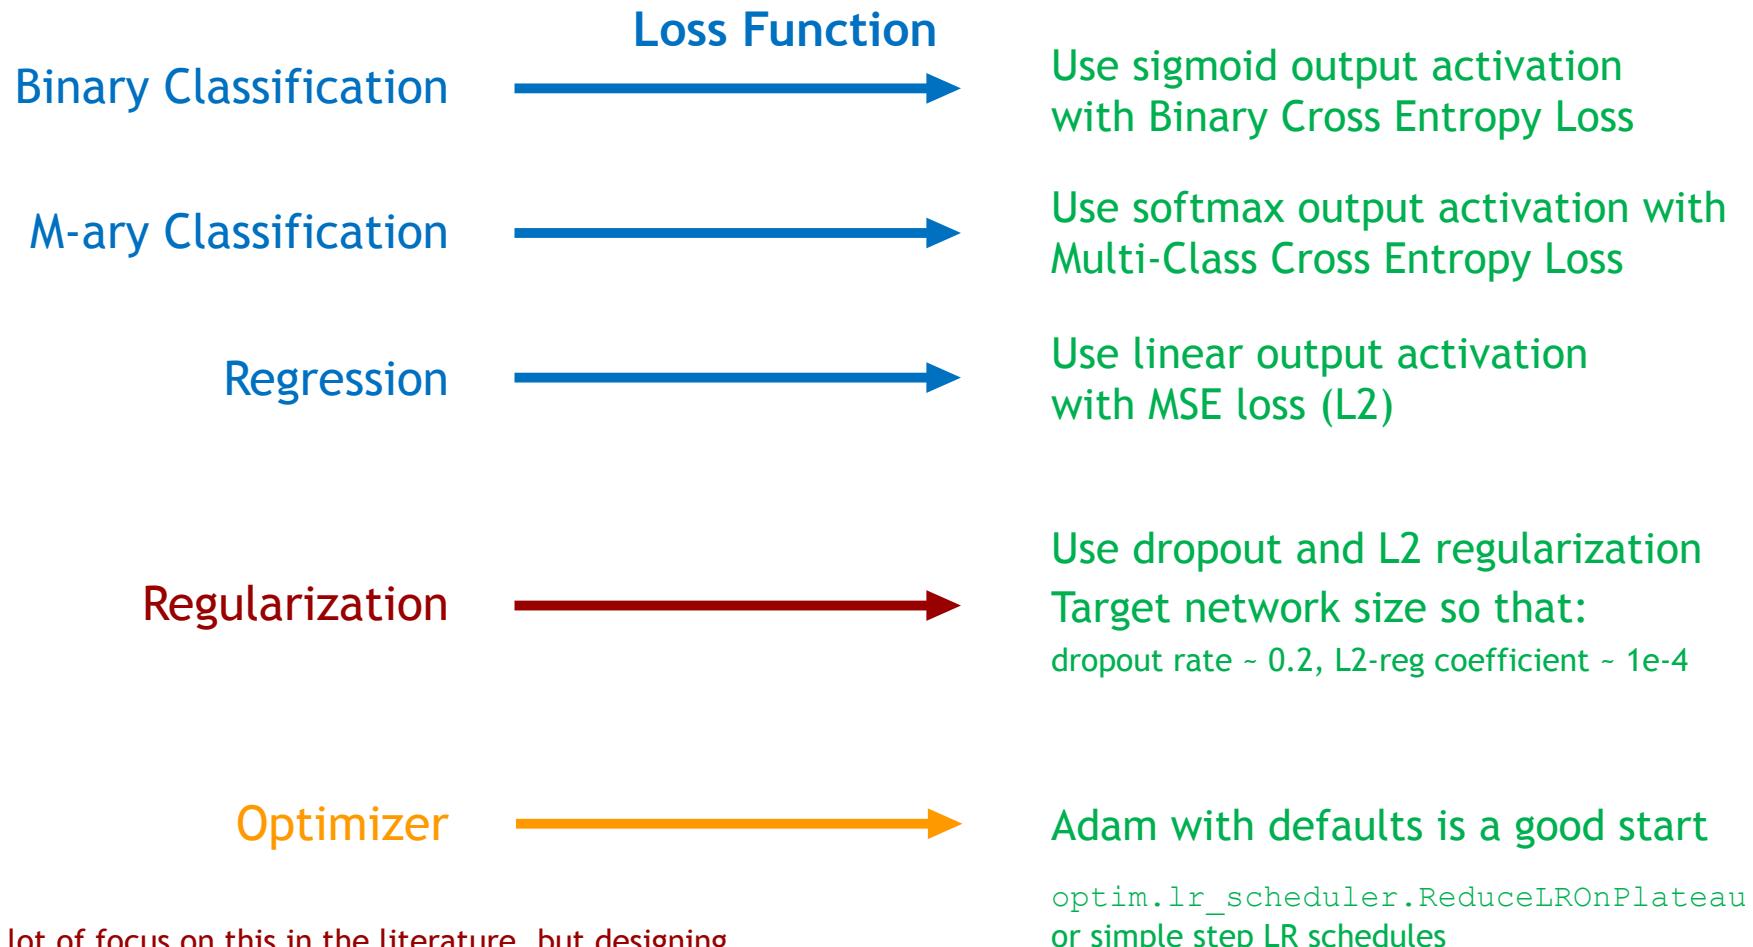

We need to search over:

1. Model Architecture
  1. Number of layers
  2. Layer types
  3. Number of nodes in each layer
2. Loss Functions
3. Regularization Methods
  1. L1, L2, L1\_L2
  2. Vary with layer
  3. Weight vs bias
4. Optimizers
  1. Type: SGD, Adam, etc.
  2. Parameters
  3. Learning rate schedules

## FOLLOW HIGH-LEVEL GUIDELINES

A lot of focus on this in the literature, but designing your dataset is more important (consider above fine tuning in practice)

# AUTOMATED NETWORK ARCHITECTURE SEARCH AND HYPERPARAMETER OPTIMIZATION

Approach combines  
Bayesian optimization with  
grid search while targeting  
a combination of  
classification accuracy and  
runtime complexity (CNNs)
